Very true as far as it goes, but Egypt and Syria both form part of the Mediterranean coast on the south and east, and yet Mr. Tozer's book tells us next to nothing about either, although so much is now known of both countries, and of the ancient intercourse which existed between them in very old times. Hieroglyphic inscriptions are extant which describe military and other expeditions to the heart of Africa and to the coasts of Arabia from the period of the sixth to the eighteenth dynasty, and several long historical texts which describe the progress of Egyptian arms in Western Asia are so well known as to make it difficult to see why Mr. Tozer has not made use of them. The Tell el-Amarna tablets, which have now been translated into English, French, and German, form a most valuable mine of information for the student of ancient geography, and yet they are not mentioned in Mr. Tozer's work. It is not yet possible to identify all the places the names of which are given in these remarkable documents, but it is quite easy to sketch the main trade and military routes between Egypt and Northern Syria, Western Mesopotamia, &c. About the fifteenth century before our era a certain Egyptian gentleman set out on a journey to Syria and, fortunately for us, he wrote an account of his experience to a friend wherein he detailed the events of the way, the names of the places at which he stayed, and several matters of considerable interest to the geographical student. M. Chabas' edition of the text and translation have been so long before the public that the Mohar's "itinerary" might well have been described by Mr. Tozer. Passing from Egypt to Babylonia and Assyria we think that enough of the early geography of these countries might have been gleaned from the cuneiform inscriptions to make two valuable chapters at least, as well as a tolerably full map.

Speaking of the pygmies (p. 30), Mr. Tozer says:

> "We may conclude therefore that the Pygmies of Homer were a real people. . . . The Egyptians might easily have heard of them, and through them the story might have found its way into Greece."

A little searching of Egyptian records would have shown him that the Egyptians knew a great deal about the pygmies, and that King Assa, about B.C. 3300, kept a pygmy, who had been brought from Central Africa by an Egyptian official called Bäurtet, at his court to dance and to amuse him. About seventy years later another king, Pepi II., sent a despatch to Heru-khuf, his officer commanding the garrison at Aswân or Syene, in which he promised him a greater reward than was conferred by Assa upon Bâurtet if he would go and bring back for him a pygmy "alive and in good health." In the inscription which covers the walls of Heru-khuf's tomb at Aswân (see Schiaparelli, "Una Tomba Egiziana," Rome, 1893), an account is given of the countries through which this brave officer passed, and though it is impossible to identify accurately all the places named, it is perfectly clear that, like the officer Una, he passed through the lands of great trees south of Khartûm, and so on to the districts described by Stanley ("Darkest Africa," i. p. 198; ii. p. 40) and Schweinfurth ("Im Herzen von Africa," ii. p. 131 ff.), to the land of the pygmies. The pygmies were so well known in Egypt that a reference to them is made in a version of the "Book of the Dead" of the sixth dynasty. In the temple at Karnak is an inscription of a later period which states that "the pygmies came from the lands of the south to do service in it," and in it, as in the earlier texts, no doubt can be entertained as to the correctness of the identification of the word *tenk* with "pygmy," for in each case it is followed by the determinative of a thick-set, stunted little man. We are hardly justified in assuming that the Egyptians had any dominion *de facto* in Central Africa, but there is no doubt that as far back as the time of the fifth dynasty they were well acquainted with the products and people of that remote land.

Again, on p. 21 the firmament of bronze which Mr. Tozer describes is nothing but the square metal plate which the Egyptians thought formed the sky and the floor of heaven, which was supported by four mountains or props placed one at each of the cardinal points; from this at night the stars were hung out like lamps, and in fact one of the names for stars, *khabesu*, means nothing but "lamp." The god Atlas is, of course, nothing but a Greek form of the god Shu, whose functions were to lift the sky up from the earth at dawn, to support it during the day, and to let it down again at night. The inscriptions of Egypt would similarly afford many an explanation of passages in Mr. Tozer's book.

Among minor matters it seems to us very doubtful if the name Samos is derived from the Semitic *shamah* (p. 5); the Arabic word *ḳasdîr* is, of course, derived from the Greek as Dozy showed (Suppl. ii. p. 355, col. 2); it is very doubtful if the names "Asia" and "Europe" are derived from the Assyrian words "to go forth" (of the sun), and "to set" (of the sun); the Peutinger Table was published in its entirety, and it is only Desjardin's description of it which is unfinished (p. 310); and we should have preferred the conical to the elliptical projection of Ptolemy's map given on the plate which faces p. 341. It only remains to say that so far as it goes Mr. Tozer's book is good, and that the classical portions of it have been carefully done; in a new edition we hope that the sources of the information which we obtain from Greek and Latin writers, and which may be traced to hieroglyphic and cuneiform records, will be duly described and set forth.

OUR BOOK SHELF.

La Teoria dei Raggi Röntgen. By Prof. Filippo Re. With two plates. Demy 8vo. Pp. 64. (Palermo: Alberto Reber, 1898.)

IN the first three chapters the author discusses the existing theories which regard Röntgen rays as longitudinal waves, molecular streams, and transverse waves of extremely short wave-length. He then proceeds to summarise the various hypotheses which have been advanced to account for the electro-dispersion of these rays, and their capability of bending round obstacles. Chapter vi. deals briefly with other kinds of new rays—namely, Becquerel rays, Le Bon's rays, and Winkelmann and Straubel's "spathofluoric" rays. A comparison of the properties of X-rays with those of Hertzian electric oscillations of considerable length, leads Prof. Re to propound the hypothesis that the former are electric waves of practically infinite length. This hypothesis, the author remarks, has close analogy with that proposed by Sir G. G. Stokes at Liverpool, who suggested that Röntgen rays might be due to non periodic disturbances of the ether.

In attempting to show how this theory accounts for the physical properties of Röntgen rays, Prof. Re has, of necessity, left unanswered many questions which naturally suggest themselves, and in answering others has hardly made out a strong case in favour of his views. He attributes absence of reflection to the great penetrating power and diffusion of the rays, and absence of observed polarisation to the impossibility of arriving at any practical result with the means commonly employed; but these explanations can hardly be said to support the present theory more than any other. To account for cryptochröism the author has to suppose that, although the waves are of practically infinite length, their lengths are nevertheless of different magnitudes. We should have liked to see the question of the magnetic deformation of Röntgen and Lenard rays discussed in connection with the present theory. Why such rays should be produced by an apparatus so different from a Hertzian oscillator as a Crookes' tube, might also well be asked.

The author's familiarity with current research affords sufficient guarantee of his competency to put forward a theory possessing certain points of novelty. We are still so much in the dark as to the nature of Röntgen rays, that every new theory is worthy of the careful consideration of physicists. Without wishing to commit ourselves, the theory of electric waves of very great length strikes us at first sight as being no less plausible than many of the other hypotheses which have been propounded.

A Text-book on Applied Mechanics. By Andrew Jamieson, M.I.C.E., Professor of Electrical Engineering in the Glasgow and West of Scotland Technical College. Vol. ii. Pp. xiii + 388. (London: Charles Griffin and Co., Ltd., 1897.)

THIS text-book, of which this is the second volume, was written mainly for second and third year students of applied mechanics. Parts i. and ii., which form vol. i., deal with the principle of work and its applications, and gearing; the present volume, divided into Parts iii. to vi., includes motion and energy, graphic statics, strength of materials, and hydraulics.

The volume is divided into fifteen chapters, called lectures, though the ground covered in any one of them is generally much greater than any teacher would attempt in one lecture and numerous illustrative examples are given at the end of each chapter. It is refreshing to find the author introducing the calculus so freely into a text-book primarily intended for science and art students. In Part iii. the author discusses very fully such important practical questions as the energy of fly-wheels, engine governors, and the balancing of moving parts: the whole section is a very complete and good one. The next section, Part iv., is entitled "Graphic Statics," and is devoted to the graphical determination of the stresses in the bars of framed structures, and to the theory on which these graphical constructions depend. The examples selected are comprehensive, and include most of the ordinary roof and bridge trusses; cranes, sheer legs, &c., are also studied. Bending moment and shear diagrams, which come very much better in Part v., are rather out of place in Lecture xxviii.; it would certainly have been far better, and less confusing to the reader, to have taken them up in the section on strength of materials, which forms Part v. of the book. This section is by no means as complete as the others preceding it. The lectures dealing with the stresses and strains in beams and shafts are full, and well worked out; but tension is treated in a very half-hearted way, while struts and their strains and stresses are simply entirely ignored: this is most unsatisfactory. It is to be hoped that in a new edition Prof. Jamieson will look to this. The omission detracts greatly from the practical value of Part v.

The last Section (vi.) is hardly entitled to the name of hydraulics, and it would have been far better to have omitted it altogether. There are only two chapters: one deals with the hydraulic plant in a modern gas-works; it is, however, almost exclusively descriptive, quite unlike all the rest of the book.

The last chapter is given up to refrigerating machinery; though what this has to do with hydraulics the author does not condescend to explain: it is, in fact, good matter in the wrong place. We confidently recommend the book to engineering students, who will find it of much use in their study of the various branches of practical mechanics touched upon by the author.

H. B.

Twenty-first Annual Report (1896) *of the Department of Geology and Natural Resources, Indiana.* By W. S. Blatchley, State Geologist. Pp. viii + 718. (Indianapolis, 1897.)

THE contents of this volume refer very largely to the economic natural resources of the State of Indiana, and embrace the results of the work accomplished by the different divisions of the Department under Mr. Blatchley's administration during the year 1896. The papers deal with the petroleum industry in the State, composition of Indiana coals, Indiana caves and their fauna, the geology of the middle and upper Silurian rocks of Clark, Jefferson, Ripley, Jennings and Southern Decatur Counties, the oölitic limestone of Indiana, the natural gas of the State, the geology of Vigo County, and the uncultivated ferns and fern allies and the flowering plants of the same county. Several excellent plates illustrate the report, and the whole volume shows that the State, which twenty years ago was noted mainly for her agricultural products, possesses great natural resources, and is rapidly assuming high rank as a mineral producing and manufacturing centre.

The Mines of New South Wales, 1897. Compiled and edited by C. W. Carpenter. Pp. 552 + lxxviii. (Sydney, London, &c.: George Robertson & Co.)

THE vast mineral resources of New South Wales may be judged by reference to this handy volume. The mines—which range from the mines of the Broken Hill Proprietary Company, with 6,512,000*l.* of dividends, to a coal mine worked by its proprietor in his spare time—are in the first place arranged geographically, and, in the case of each, particulars are given—as the proprietors, development, yields, area, &c. In the geological section of the book the mines are arranged under the names of the minerals obtained from them. The remainder of the volume is taken up with descriptions of batteries and ore-reducing works, and lists of directors of mining companies, New South Wales mining patents, and an alphabetical list of mines.

LETTERS TO THE EDITOR

The Submerged River-Valleys and Escarpments off the British Coast.

IN connection with the observations of American geologists—especially those of Prof. J. W. Spencer and Mr. Warren Upham—on the "drowned" terraces and cañons of the American coast, the eastern borders of the North Atlantic afford some interesting results when examined with the aid of the Admiralty charts. It has long been known from the researches of the late Mr. Godwin-Austen, Prof. T. Rupert Jones, and others, that the British Isles are planted on a platform, of about 100 fathoms near its margin, and known under the name of "the 100-fathom platform." I am now engaged on a careful study of this physical feature, and the results, though as yet incomplete, are of such interest that I may be permitted to place them briefly before your readers. By tracing the contours, which may be drawn on the chart of the British Isles from the neighbourhood of Rockall as far south as the entrance to the Bay of Biscay by the aid of the very numerous soundings, two well-marked features may be recognised. The margin of the platform is very nearly defined by the 100-fathom line off the coast of Scotland, where it terminates along "the Vidal Bank"; but from this level it gradually falls away southwards, till at the entrance to the Bay of Biscay it reaches the 200-fathom contour; from this margin the floor of the ocean gradually slopes upwards to the coast, so as to constitute a shelving plain with little interruption. West of the coast of Ireland the platform is as broad as Ireland itself; that is, about 200 miles at its greatest breadth; and here it breaks off in a magnificent escarpment of no less than about 1300 fathoms (7800 feet) in height, its base giving place to a second gently sloping plain from 1500 to 2000 fathoms; or 9000 to 12,000 feet in depth, leading down to abyssal regions. This grand escarpment of about 7000 feet in height is continuous with the Vidal Bank, and opposite the English Channel bends sharply round to the eastward, in some degree conforming to the outline of the land. That this escarpment was once an emergent physical feature, corresponding to those of Eastern America, now submerged, or of the now unsubmerged terraces of Colorado, is a deduction of which I am now absolutely convinced, notwithstanding the stupendous physical changes which the deduction involves. We will now proceed to consider briefly some evidence of a corroborative kind, from which I cannot see any possibility of escape; I refer to the existence of river-valleys now traceable across the British platform, and opening out into gorges on approaching the edge of the escarpment. Some of the existing river-courses, like those of the Severn and the Kenmare rivers, are somewhat obscurely indicated by the soundings across the platform; but there are two distinctly traceable river-courses which are now altogether submerged: the first descending from the Irish Channel; the second through the English Channel. Assuming for a moment, what will scarcely be denied, that the platform down to a depth of 100 to 200 fathoms was formerly a land surface, it is clear that the streams entering from the existing lands must have had an outlet by means of rivers entering the Atlantic westwards. The examination of the soundings shows that this drainage was effected by means of two large rivers running near the centre of these channels, receiving the streams from either side. On tracing them across the platform, and on approaching the edge of the escarpment, we find the channels rapidly deepening, and within a mile or two of the edge taking the form of deep and narrow gorges, ultimately broadening out into "embayments," descending down to the very base of the escarpment itself; a condition corresponding to the "base levels of erosion" of the American geologists; and also represented by some of the Scandinavian fjords. Such physical features are altogether terrestrial. It is impossible (as it seems to me) that they could have been originated while the region referred to was in its present condition of ocean-bed. One portion of the river-valley which drained the English Channel is very clearly indicated on the chart under the name of the "Hard Deep." This gorge, about a quarter of a mile broad and seventy miles in length, occupies that narrow part of the channel between Cape de la Hague on the coast of France and the Bill of Portland. Throughout the course of this old river-valley over the platform the channel has, to a great extent, been choked up and nearly obliterated by the deposit of sediment constantly going on for long ages; but along this part of its course, owing doubtless to the force of the tidal currents due to the narrowness of the channel, the sediment has apparently not been able to accumulate; hence the well-defined banks of rock which the soundings disclose. As regards the submerged channels of the existing rivers entering the Atlantic westwards, only faint indications can be obtained from the soundings; nor is this surprising when we recollect that the North Sea, the Irish Channel, and portions of the ocean bordering the north-western coasts of the British Isles have been covered in part by land ice, and altogether by the muddy waters of the later glacial seas, giving place to those of the present day; the mud, sand and shingle thus deposited have sufficed to cover the old floor of the platform for many feet in depth in most places, and to fill up the channels of the streams formed during earlier emergence. The total distance from north to south through which these observations extend is about 500 miles. I hope to be able to return to the subject later on. EDWARD HULL.

The Use of Compressed Coal Gas.

IT may be of interest to users of the limelight to put on record the following occurrences.

A 40-feet cylinder was filled with coal gas at a pressure of 120 atmospheres by a leading London firm on March 15, 1897; a small quantity was used, and the cylinder stood till October 9. It was then used for a mixed jet, and at the end of half an hour the light began to decrease, and in another quarter of an hour practically no gases were issuing. On relighting the jet the light was found perfect, and the fault was ascribed to the Beard's regulator.

The cylinder was again used on March 5 last, and again after half an hour the light began to fail; but on turning the taps full on something audibly blew out of the nozzle, and the light was perfectly restored.

The lime blackened excessively: while white-hot, the "hydrogen" was turned off and the oxygen allowed to play on it, when the deposit turned a brilliant orange-red.

The coal gas was then passed through a glass tube gently heated in a Bunsen flame—a copious metallic mirror which gave the test for iron was formed.

It seems probable that the jet was choked by the decomposition of iron carbonyl at the high temperature. In any case there is an obvious disadvantage in storing for a considerable time compressed coal gas in steel cylinders, altogether apart from the possible damage to the cylinders, which has been shown to be small. C. E. ASHFORD.

Harrow, March 19.

THE SCIENCE BUILDINGS AT SOUTH KENSINGTON.

SINCE the nation acquired, a good many years ago now, a plot of ground from the Royal Commissioners of the Exhibition of 1851, at a cheap rate, on which to erect buildings to foster teaching and research in Science and Art, there have been many schemes put forward, but nothing done, till at last the teaching of Science has become desperate. The Government have known this fully, and a few years ago plans were designed to bring to a head the various schemes by erecting Science buildings on the west side of Exhibition Road, and the Art buildings on the east side, an allocation of the spare land which had been accepted in principle by everybody.

But now it appears there has been a sudden *volte face*. Seeing that *at the present* moment Art does not require all the space at its disposal on the east side, the interstices are to be filled up with certain of the science buildings as we gather from the statement made by the First Commissioner of Works, on Thursday last: "The Government asked for the large sum of 800,000*l*. for the completion of the buildings at South Kensington in connection with Science and Art. He was quite certain that the Committee would admit that the settlement of this question had been demanded both by the House and by the public for many years past. In 1891 the decision was come to to proceed with the building to complete the accommodation for the Art Museum, and for housing the administrative departments of Science and Art. Plans were accordingly prepared by Mr. Aston Webb, and accepted, for a building to occupy the land on the south side of the Museum facing the Cromwell Road; but the sources at the disposal of Chancellors of the Exchequer, on both sides of the House, unfortunately did not permit of the grant of the necessary funds, and the scheme had since then been in abeyance. Since that scheme was formulated, and partly in consequence of the report of the Commission on Secondary Education, it was in contemplation to move to the Education Office the secretariat of the Science and Art Department, and further—in accordance with the recommendation of the Select Committee of last year on the South Kensington Museum—it was decided to remove the official residences and certain other temporary buildings, which were a source of danger from fire. With this additional space at disposal, it would now be possible to provide on the eastern side of Exhibition Road the necessary accommodation for both Science and Art. It was, therefore, intended to build, in addition to the building proposed in 1891, further buildings which would complete the frontage on the Cromwell Road and Exhibition Road sites; and, in the opinion of the Government, that would amply meet the requirements of both branches for many years to come."

On this proposal the *Times* remarks:—

"How far these projects, which the Government regard as all that can be reasonably demanded, will be satisfactory to those who take more than an official interest in the matter it would be premature to speculate."

We do not think it "premature" to state that it is to be hoped that the Government before they go further in this matter will obtain some opinions from men of science. The suggestion appears little short of disastrous, having regard for the future representation of scientific teaching and illustrations in our National Institutions, for surely the Empire will outlast another century. These remarks are not made because the sum asked is too little, for we do not believe a Committee, say of the Royal Society, or the President and Council of the Society itself, appointed to consider the matter, would see its way to spend more than 250,000*l*. to cope with the present needs of Science.

SKIAGRAPHY AFTER INJECTION OF THE BLOOD VESSELS WITH MERCURY.

TO elucidate the relations of the various opaque structures of the body to one another whilst undisturbed by the processes of dissection, is one of the numerous uses to which skiagraphy has been applied.

It is obvious that this process may be extended to the blood vessels in the dead body by filling them with some medium which is opaque to the X-rays, and in this way their relative situations to each other and to the bony skeleton may be studied with facility. Various experimenters have occupied themselves with the task of producing such skiagraphs, and amongst a considerable number who have obtained successful pictures may be mentioned Dutto, Raw, and Remy and Contremoulins, the former of whom employed a plaster injection mass, the latter one of wax in which bronze powder was suspended.

These results, though sufficiently encouraging, were not wholly satisfactory, and one of us (H. J. S.) determined to follow out a method which he had devised before he became acquainted with the work of other observers, and in which metallic mercury had been selected as the substance to be injected. The results of our experiments with it have been most satisfactory, and it seems probable that with the greater experience which we have now gained in the methods of carrying out the details of the process, still better work may be done than has yet been accomplished.

The plan which has been adopted is very simple. The blood vessels of the part to be injected are well washed out with a solution of six parts of common salt in a thousand parts of water, and the mercury is then injected by inserting into the principal artery a canula connected with a small reservoir of the metal by a piece of rubber tubing. Care must be exercised to prevent the presence of air in the tubing or canula, and the mercury should be injected at a moderately low pressure, which naturally varies in different cases, but as a general rule may be taken at about 30 to 50 mm. of mercury. If the pressure is excessive there is considerable risk that the resistance which the capillaries offer to its advance will be overcome, and the veins will be filled as well as the arteries. One very important detail is that the injected specimen should be moved as little as possible after the injection has been effected, as any shaking or change of position is apt to cause breaks to occur in the column of mercury, and thus to interfere with the success of the skiagraph.

We have also found that if the specimen has to be kept for some time before the injection is made, one can preserve it very satisfactorily by filling the blood vessels with a 5 per cent. solution of formalin, which in no way interferes with the subsequent injection, except that it lessens somewhat the calibre of the vessels.

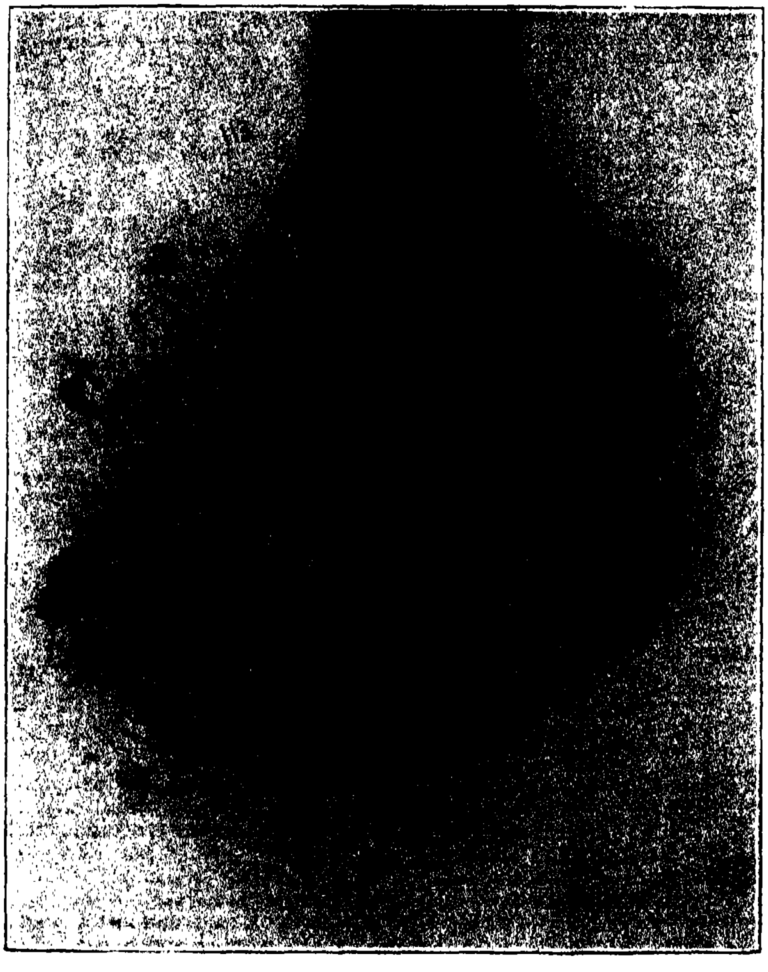

Fig. 1.—Arteries of head and brain in a child.

The skiagraphs have been taken in the ordinary way; the authors have employed a 10-inch spark "Apps-Newton" coil, and, as a rule, ordinary focus tubes supplied by Mr. Newton, which they have found very satisfactory. Of the illustrations which accompany this paper, Fig. 1 represents the arterial system of the head of a child. The brain is *in situ* within the cranium, and the whole is injected through the carotid artery in the neck. The very abundant blood supply to the basal ganglionic masses of the brain is well shown, and it is interesting to note the great tortuosity of the internal carotid arteries as they pass through the base of the skull, by which the force of the sudden rise of blood pressure on the advent of the pulse wave is reduced so far as to prevent an undue strain being thrown on the delicate structures within the cranium. In order to prevent the escape of mercury through the several vessels in the neck, the head was placed upside down upon a small beaker, whose shadow appears in the photograph; where large vessels had been severed, clamp forceps were applied.

The other illustration (Fig. 2) shows the result of an injection of the branches of the system of the superior vena cava. The subject in this case was a young child, and the incomplete ossification of the bones, especially near the joints, may be incidentally noted.

In this instance the body was placed lying on its back on the photographic plate, whilst the Röntgen lamp was fixed in front of the chest; and therefore the anterior part of the bony skeleton is rendered indistinct, whilst the vertebral column and posterior portions of the ribs are relatively prominent. The injection has filled the main branches of the superior caval vein and the spinal veins, and it has penetrated also into the right auricle and ventricle, from which it has reached the larger divisions of the pulmonary artery.

It must be remembered, in identifying the various structures in the photograph, that when a print is taken from a negative the relations of the parts are reversed as in a mirror image, and thus what is really on the right-hand side in the specimen appears on the left in the print, and *vice versâ*. This can, when desired, be obviated either by producing the print by the single transfer carbon process, or by taking the original skiagraph with the film side of the negative furthest from the subject. In this case, since glass considerably obstructs the passage of the X-rays, the negative should be on a celluloid support, and the sensitised surface may be laid upon a fluorescent screen. When this is done, the rays after having penetrated the film are still further utilised by inducing fluorescence of the screen, which in its turn acts on the emulsion of the negative. The result of the manœuvre, though somewhat shortening the length of exposure, seems to render the resulting impression rather less sharp in its definition.

A point which must impress any one who looks at these photographs is the extraordinary vascularity of the tissues of the body, and one might reasonably wonder how comparatively small wounds, to say nothing of the large and deep incisions which are required in the course of many surgical operations, do not inevitably lead to the death of the sufferer by hæmorrhage. The reply to this is, that did the prevention of hæmorrhage depend solely on the efforts of the surgeon, there is little doubt that even small wounds would prove inevitably fatal; but provision has been made by nature to meet the emergency, and the bleeding is largely stopped by what is known as the natural arrest of hæmorrhage.

It is not possible to describe this process in detail in the present paper, but the main elements involved are the fact that blood on escaping from the vessels tends to coagulate, and so forms a plug which prevents further escape, and that the severed vessel retracts up its sheath so that the plug is more efficiently supported, whilst the diameter of the vessel is itself greatly reduced by the contraction of the muscular elements in its walls. By these means the blood flow is temporarily checked, and as the wound gradually heals, secondary changes occur in the cut vessels which lead to their permanent occlusion.

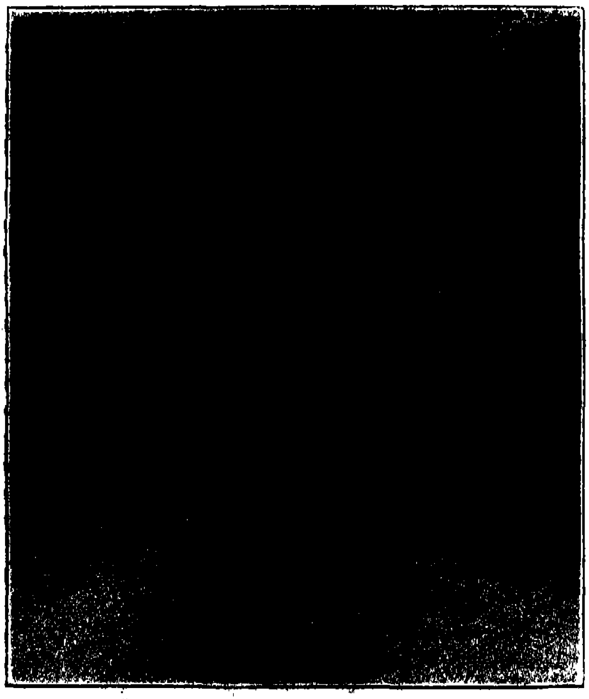

FIG. 2.—Injection of veins in chest.

Another fact that is well illustrated in such skiagrams is the extreme freedom of anastomosis between many of the smaller vessels which arise at different points of the chief arteries. It is this system of anastomosis which permits surgeons to ligature the main artery of a limb without running serious risk of mortification following the operation; as the blood, unable to pass by its ordinary channels, dilates the smaller vessels which bridge the occlusion, and thus establish an efficient collateral circulation in the course of a brief period after the ligature has been applied.

H. J. STILES.
H. RAINY.

SIR HENRY BESSEMER, F.R.S.

THE death of Sir Henry Bessemer, announced last week as we went to press, removes a leading representative of the world of applied science, and one whose inventions revolutionised a manufacturing process. Henry Bessemer was born in 1813 at Charlton, in Herts, and was thus eighty-five years of age at the time of his death. From his father, who was an artist and a member of the French Academy of Sciences, he seemed to have inherited certain artistic tendencies, for at an early age he showed a fondness for modelling and designing patterns. He soon, however, turned his attention to other matters, and began the long series of inventions which carried him on to fortune. His success commenced with the invention of a means of manufacturing bronze powder or "gold" paint from Dutch metal. This invention laid the foundation of his fortune, and it was the profits of the manufacture of the bronze powder which enabled him to carry on experiments in the metallurgical process which bears his name.

Bessemer's first experiments to improve the quality of iron were made in 1855. He was not an iron manufacturer when he began his work, neither was he a metallurgist. But he possessed the true instincts of an investigator, for he was quick to observe and sound in his deductions; and the man who possesses and utilises these qualities is a man of science, whether he has had a systematic training in theoretical principles or not. His own account of the observations and reasoning which led to the idea of the Bessemer process is interesting. While making experiments with iron in the open-hearth furnace, the following incident occurred:—

"Some pieces of pig iron in one side of the bath attracted my attention by remaining unmelted despite the great heat of the furnace, and I turned on a little more air through the fire-bridge with the intention of increasing the combustion; on again opening the furnace door after an interval of half an hour, these two pieces of pig still remained unfused. I then took an iron bar with the intention of pushing them into the bath, when I discovered that they were merely thin shells of decarbonised iron, thus showing that atmospheric air alone was capable of wholly decarbonising grey pig iron, and converting it into malleable iron without puddling or other manipulation. It was this which gave a new turn to my thoughts, and after due consideration I became convinced that if air could be brought into contact with a sufficiently extensive surface of molten crude iron the latter could rapidly be converted into malleable iron."

On August 13, 1856, Bessemer read a paper at the Cheltenham meeting of the British Association, entitled "The Manufacture of Malleable Iron and Steel without Fuel," this being the first account that appeared shadowing forth the important manufacture since known as the Bessemer process. The paper, however, was not printed in the Association's Report for 1856, and the title, where mentioned, it may be noted, is quoted without the word "malleable." It was followed, in 1865, by a long communication, read at the Birmingham meeting, "On the Manufacture of Cast Steel; its Progress and Employment as a Substitute for Wrought Iron." Sir W. (now Lord) Armstrong, the President of the Section, in referring to it, remarked as follows:—"The paper from Mr. Bessemer upon steel cannot fail to be highly valued by the Section. The growing importance of this material, and its rapidly extending sphere of usefulness, have attracted attention in a special degree to the question of economy in its production; and certainly no one has contributed so largely as Mr. Bessemer to our advance in this direction."

The first honorary recognition of the importance of the Bessemer process in this country was made by the Institution of Civil Engineers in 1859 by the award of the Telford medal. In 1871-73 he was President of the Iron and Steel Institute, and in 1872 he received the Albert medal of the Society of Arts "for the eminent services rendered by him to Arts, Manufacture, and Commerce, in developing the manufacture of steel."

In 1874 he was a member of a Committee appointed to consider what steps could be taken in furtherance of the use of steel for structural purposes, and signed the report, which was issued in March 1877. He was elected a Fellow of the Royal Society June 12, 1879. His certificate of claim is probably as short as any ever set forth for candidature, bearing, as it does, the single sentence, "Discoverer of the Bessemer process of making steel." In the same year he received the honour of knighthood, and in 1880 was presented with the freedom of the City of London. From abroad he received many honours. He was offered the Grand Cross of the Legion of Honour; but as permission to wear it was refused, he had to be content with a large gold medal given him by Napoleon III. He was an honorary member of the Iron and Steel Board of Sweden, a freeman of the City of Hamburg, an honorary member and gold medallist of the Society of Arts and Manufactures of Berlin, and a Grand Cross of the Order of H.I.M. Francis Joseph of Austria.

His written contributions to science were very limited. The Royal Society's "Catalogue of Scientific Papers" contains one other besides the two already given, viz. "On the Resistance of the Atmosphere to Railway Trains and on a means of lessening the same" (*Franklin Inst. Journ.*, vol. xiv., 1847). It is in connection with his metallurgical labours that his name will go down to posterity; and as an inventor who refused to be discouraged by obstacles, and pertinaciously held on to a scheme until it carried him to success.

NOTES.

A SPECIAL meeting of the Royal Society will be held in the rooms of the Society at Burlington House on Thursday, March 31, at 4.30 p.m., to receive preliminary statements as to the results of observations made during the recent total solar eclipse. Communications will be made by the Astronomer Royal, Sir Norman Lockyer, K.C.B., and other gentlemen.

MR. CHREE'S communication in another column relating to the present disturbed magnetic conditions is most interesting in relation to the recent eclipse. The remarkable association of a great number of sun-spots was connected in the telegrams from Viziadurg with the brightness of the corona, and the absence of the equatorial extensions seen at the period of minimum sun-spots. The wonderful chemistry of the spots may also be referred to recent observations indicating chiefly the presence of scandium and vanadium. Magnetic storms and auroræ therefore are little to be wondered at. Were there any indications in January and February?

AT the meeting of the British Association held at Toronto last year, a resolution was passed by the general committee, requesting the Council to consider the desirability of approaching the Government with a view to the establishment in Britain of experimental agricultural stations similar in character to those which are producing such satisfactory results in Canada and elsewhere. This proposal was referred by the Council to a special committee, which has since made a report. The committee, while agreeing that some central institution might be of great use in the improvement of agriculture in this country, pointed out that there are already a number of independent bodies, connected with agricultural societies, colleges, and county councils, which are conducting agricultural investigations, and that it would be undesirable to approach the Government without the co-operation and support of these various bodies. The Council of the British Association has accepted this report, and has requested the committee to communicate with the various institutions interested in agriculture throughout the country, and to ascertain their views upon the subject. We are informed that the committee are now in communication with the various institutions referred to, in order to obtain a combined opinion upon the desirability of the creation by the Government of a central agricultural institution, for the purpose of undertaking agricultural research, and of acting as a centre of union for the various bodies conducting similar researches in this country, and of affording them advice and assistance when desired.

THE following officers of sections have been appointed for the Bristol meeting of the British Association:—Section A—President: Prof. W. E. Ayrton, F.R.S. Vice-Presidents: Prof. Rücker, F.R.S., Prof. S. P. Thompson, F.R.S. Secretaries: Prof. A. P. Chattock, Prof. W. H. Heaton (Recorder), J. L. Howard, W. Watson, E. T. Whittaker. Section B—President: Prof. F. R. Japp, F.R.S. Vice-President: Prof. W. Ramsay, F.R.S. Secretaries: Dr. C. A. Kohn (Recorder), Dr. T. K. Rose, F. Wallis Stoddart. Section C—President: W. H. Hudleston, F.R.S. Vice President: E. Wethered. Secretaries: G. W. Lamplugh, Prof. H. A. Miers, F.R.S. (Recorder), E. Wilson. Section D—President: Prof. W. F. R. Weldon, F.R.S. Vice-Presidents: Prof. F. Gotch, F.R.S., Prof. L. C. Miall, F.R.S. Secretaries: W. Garstang, Dr. A. J. Harrison, W. E. Hoyle (Recorder). Section E—Vice-Presidents: Colonel F. Bailey, Dr. J. Scott Keltie. Secretaries: H. N. Dickson, Dr. H. R. Mill (Recorder), A. J. Herbertson, H. C. Trapnell. Section F—President: Dr. J. Bonar. Vice-President: Prof. E. C. K. Gonner. Secretaries: E. Cannan, Prof. A. W. Flux, H. Higgs (Recorder), W. E. Tanner. Section G—President: Sir John Wolfe-Barry, F.R.S. Vice President: G. F. Deacon. Secretaries: Prof. T. H. Beare (Recorder), H. W. Pearson, W. A. Price, Prof. John Munro. Section H—President: E. W. Brabrook, C.B. Vice-President: C. H. Read. Secretaries: H. Balfour, J. L. Myres (Recorder), Dr. G. Parker. Section K—President: Prof. F. O. Bower, F.R.S. Vice-President: Prof. H. Marshall Ward, F.R.S. Secretaries: A. C. Seward (Recorder), Prof. J. B. Farmer, J. W. White.

SIR GEORGE KING has retired from the superintendentship of the Royal Botanical Gardens, Calcutta, and has been succeeded by Surgeon-Major David Prain.

THE Bakerian Lecture will be delivered at the Royal Society this afternoon by Dr. W. J. Russell, F.R.S., the subject being "Further experiments on the action exerted by certain metals and other bodies on a photographic plate."

THE centenary of the discovery of the voltaic pile will shortly be celebrated at Volta's birthplace on Lake Como.

M. ÉMILE PICARD, member of the Paris Academy of Sciences, and professor of higher algebra in the University of Paris, has been elected corresponding member of the Berlin Academy of Sciences.

DR. LUDWIG MOND, F.R.S., has been elected a member of the Athenæum Club, under the rule which empowers the Committee to elect annually nine persons "of distinguished eminence in science, literature, the arts, or for public services."

THE annual meeting of the Iron and Steel Institute of Great Britain will be held in London on Thursday and Friday, May 5 and 6. At this meeting the Council will present their annual report for 1897, and a number of papers will be read and discussed. The autumn meeting of the Institute will be held at Stockholm, under the auspices of the Swedish Association of Ironmasters, on Friday and Saturday, August 26 and 27.

THE Academy of Mathematical and Physical Sciences of Naples offers a prize of 500 lire for the best memoir on some subject connected with stereo-chemistry. The essays, which must be in Italian, Latin or French, must be sent in to the Secretary of the Academy not later than June 30, 1899. A prize of 1000 lire has just been awarded by the Academy to Prof. Giuseppe de Lorenzo for his essay on the pleistocene lakes of Southern Italy.

THE Royal Academy of Sciences of Bologna announces that a gold medal in memory of Aldini will be awarded in 1899 for the best essay on galvanism (animal electricity). The essays may be either in Italian, French or Latin, or may be in any other language, provided the author sends in a translation in one of these languages. They may either be in manuscript or printed, provided that in the latter case their publication has taken place within the two years preceding the award. Papers competing for the prize are to be sent before May 29, 1899, addressed to the Secretary of the Royal Academy of Sciences of the Institute of Bologna.

PROF. B. BRAUNER, of Prague, addressed an extraordinary meeting of the Chemical and Physical Society of University College, London, on Friday, March 18, and gave an account of his investigations with regard to the elements thorium, praseodymium and neodymium, his revision of the atomic weights of the latter elements, and their probable positions in the periodic table. In concluding his address, Prof. Brauner drew attention to the scientific importance of further investigation among the rare earths, and expressed a hope that more chemists would enter this field of research, which promised results of the highest value. In proposing a vote of thanks, Prof. Ramsay pointed out that the work, of which an account had been given, was a monument of careful experiment and extraordinary industry. Although it might appear to many present that an enormous amount of labour had been expended on an obscure corner of chemistry, it must be remembered that it was precisely such work which bore on the whole of chemical theory; and, indeed, which might be expected to influence chemical manufactures at a future date. It was possible that in the middle of the next century these researches of Prof. Brauner might bear fruit in extensive industrial application, and that these researches might become household words in the mouths of future generations of chemists. Prof. Tilden, in seconding the vote of thanks, desired in the first place to offer to the Society his own thanks, and those of his colleagues and students who were present, for the courteous invitation which had been extended to them. He congratulated Prof. Brauner on the success which so far had attended his labours, to which he had brought so large a supply of patience and perseverance, and in framing his hypotheses so much of the inspiration of the poet. In regard to the origin of these strange elements, the choice seemed to lie between the notion that they represented the ruins of a former state of things, or they might stand for those "old worn particles" referred to by Descartes, and on the other hand the idea that they resulted from the condensation of the original protyl; though in some way the process differed from that which gave rise to the rest of the elements. With regard to cobalt and nickel, which had been mentioned, he thought it probable that their atomic weights would ultimately turn out to be not quite so nearly identical as sometimes supposed. At the close of the meeting Prof. Brauner exhibited the absorption spectra of salts of praseodymium and neodymium, and a number of specimens of the pure salts.

AT a meeting of the Associated Chamber of Commerce, on March 17, Sir H. Stafford Northcote, Bart., M.P., in the chair, the following resolution was carried unanimously:—"That, in the opinion of this Association, the compulsory adoption within some limited period of the metric system of weights and measures legalised by the Act of last Session be advocated by every possible means, with the view of inducing Her Majesty's Government to afford facilities for the amendment of the law in this respect, and that a copy of this resolution be sent to the President of the Board of Trade and to the First Lord of the Treasury. This Association urges the Government meanwhile to adopt the metric system of weights and measures, as far as possible, in all Government contracts and returns, so as to make it familiar to the people; and recommends individual Chambers of Commerce to press the matter upon the attention of local governing bodies, to the end that these also may employ the system in all public contracts, and thus facilitate its general adoption."

WORK has just been begun upon a new building—the Horniman Free Museum—which Mr. F. J. Horniman, M.P., intends to present to the inhabitants of Dulwich and the neighbourhood. Several years ago Mr. Horniman filled a house at Forest Hill, London, with curios and objects of natural history, and made this museum free to the public. He now proposes to house the collections more elaborately, and it is for this purpose that the new building is to be erected. The building will contain two lofty galleries, each 100 feet long, lighted from the top. In addition, there will be a large lecture theatre capable of seating 300 people. The galleries will be divided into various courts, each devoted to a separate class of objects. Special provision will be made for the zoological and entomological specimens. Around the site of the new museum Mr. Horniman has purchased fifteen acres of ground, which he intends to convert into a public park and recreation ground. One of the mansions at present occuping the site is to be fitted up as a free library and club house, separate rooms being devoted to the free use of the scientific and other clubs in the neighbourhood.

THE *Athenæum* announces that the Accademia dei Lincei has chosen Prof. Eugenio Beltrami as president, in place of the late Prof. Brioschi. The new president of the most important scientific society in Italy, like his predecessor, is a mathematician. He is a native of Cremona, sixty-three years old, and has enriched his special branch of literature with a series of works on differential geometry, electricity, and magnetism. He is at present occupied with the editing of Leonardo da Vinci's "Codice Atlantico."

SOME few years ago the attention of readers of NATURE was directed to the then very remarkable utterance of an Oxford theological tutor on the subject of evolution. We refer to the late Canon Aubrey Moore. We now quote a striking passage by another Oxford teacher, whose sincerity and philosophic acumen are becoming generally recognised—the Rev. Charles Gore, Fellow of Trinity College, Oxford, and Canon of Westminster. The lecturer, after referring to the extraordinarily free way in which St. Paul quotes the Old Testament, says that: "Thereby we learn a lesson which we have got to learn, that Divine revelation does not include critical methods. God leaves us to the critical methods natural to every age, and each age must readjust its criticism. What God does give us is a moral and spiritual revelation of His own being and of our being, of our destiny and of our sin, and a revelation of the Divine means that God has taken for our recovery; and we have got to learn that lesson. Divine revelation is in the things of faith and morals—as we say, is of spiritual things; and we only bewilder our intelligences and cause stumbling-blocks if we try to assert that Divine revelation is given of these matters of natural science which progress from age to age by human investigation." The passage is quoted from a verbatim report in the *Guardian*, as it was delivered in Westminster Abbey to a crowded audience of thoughtful men on March 11, during Canon Gore's third Lent lecture on the epistle to the Romans.

IN *Annalen der Hydrographie und maritimen Meteorologie* for February, Dr. W. J. van Bebber has an article on weather prediction, with especial reference to the storm signal service on the German coasts. The author lays stress upon the difficulty of obtaining a clear idea of the success of weather predictions in different countries owing to the various methods of checking them, and thinks that the only safe criterion is the opinion of the public most interested in them. He makes various proposals for the improvement of the forecast, most of which have been previously considered, *e.g.*: (1) The extension of telegraphic communication to islands in the North Atlantic. (2) The introduction of the so-called circular system of communication, by placing the principal stations and central offices throughout Europe in direct telegraphic correspondence with each other, immediately after the observations are taken. (3) More frequent telegrams, and where possible the establishment of telemeteorographs, or instruments reporting the chief meteorological elements continuously to the central offices. This arrangement already exists at a few places on the continent. (4) A direct exchange of telegrams between various signal stations. (5) The adoption of means for more generally disseminating the principles of weather conditions among the public, and the publication of an atlas containing types of weather, by means of which telegraphic reference to conditions similar to those actually existing might be made, without waiting for the publication of weather charts, as at present. The serious question of expense underlies the adoption of any of these suggestions.

The Industrial Commission, appointed by the Lieutenant-Governor of the Isle of Man, to consider the best means of promoting new Manx industries, received from Prof. Herdman, at a meeting held last week, some important evidence relative to encouraging Manx sea fisheries, spawning beds, and hatcheries. Prof. Herdman expressed the opinion that the failure of the herring fisheries was more due to natural causes, such as the absence of food or changed meteorological conditions, than to overfishing or other cause that could be controlled. He did not think that fish were scared away, because the herring was a most tenacious fish, and would go where it wanted in spite of great difficulties. He did not think that steam trawlers did much harm by destroying spawn. On the contrary, they rather did good by catching the fish (haddock) that lived on herring spawn. He agreed that the three-mile limit was a good rough and ready method of preserving young fish. To obtain any other method of protection would require international law. With regard to hatcheries, he favoured the establishment of hatcheries for cod, plaice, and white sole at Port Erin, and oyster beds at Derbyhaven.

An interesting report has been made to the Essex Technical Instruction Committee by Mr. T. S. Dymond, the Staff Lecturer on Chemistry, on the damage done to the land by the salt-water flood due to the injury of the sea-banks by the gale and high tide of November last. From this report it appears that round the coast of Essex alone about 50,000 acres of land were flooded by the overflowing of the salt water. Upon some of the farms the water only remained a few hours; other land was flooded for six or eight days; and in some cases the sea walls have not been repaired, and the water flows over the land during spring tides. This land in its ordinary condition contains only ·01 per cent. of salt, whereas the flooded land is found by analysis to contain ·20 per cent., equal to two tons an acre in the top six inches of soil. This excess of salt is injurious to vegetation. Peas and tares have suffered severely, wheat has been damaged to a less extent, and where the seed had not germinated does not seem to have been affected. The most serious and more permanent effect, however, is due to the effect of the salt on the earthworms, which after the flood were found strewn upon the surface of the ground, whence they were carried off by the gulls. The use of worms in assisting the drainage and promoting aeration of the soil is universally recognised, and their extermination in the heavy flooded land is therefore a serious matter. The sea salt also, owing to its power of absorbing moisture, renders the soil moist and difficult to work, and also prevents the aeration which is necessary to the roots of the plants, and for promoting fermentation of humus, and nitrification. The injury to the land by the destruction of the earthworms was a fact generally accepted as correct in the inundation due to an exceptionally high tide which covered a large area of the Lincolnshire Fens with salt water at the beginning of the present century.

A specimen copy of a new French scientific journal has been sent to us, entitled *Archives de Parasitologie.* As its name implies, it is hoped it may become the organ of researches dealing with parasites capable of provoking disease in both man and animals. The editor is Raphael Blanchard, Professor at the Faculty of Medicine of Paris, and he hopes by admitting memoirs in German, English, Spanish and Italian, to encourage foreigners to send their work for publication in his journal. It will appear quarterly, and no pains, it is stated, will be spared to ensure the printing and illustrations being of the best possible character. In connection with the subject of parasitic disease, there is an interesting little article—"Notes on the life-history and microscopic appearances of the parasite of Malaria," by A. E. Griffin—in the current number of the *Middlesex Hospital Journal.* Although the parasite of malaria was discovered and described by Laveran as long ago as the year 1880, its life-history has by no means been yet thoroughly worked out. It is, however, supposed that mosquitos may play an important part in the evolution of this parasite, and that, present as an encysted form in the eggs of these insects, the germs may be introduced through the medium of air or water into the human body; or a mosquito which has become infected with the blood of a malarial patient may attack and infect a human being directly. The medium of infection is generally supposed to be through the air; but there is strong evidence that water may also convey the disease, and Mr. Griffin cites cases of malaria contracted on a ship which, touching at Colombo, took in water there, and twelve days later, the usual incubation period, the disease manifested itself on board. Arsenic in large doses, it appears, proved a more valuable remedy than quinine in the late Ashanti war.

Dr. F. von Kerner contributes a paper on the geography of the middle course of the river Kerka to the *Mittheilungen* of the Vienna Geographical Society. The Kerka ceases to be navigable at the falls of Scardona, and above that point its course is impeded by many falls and rapids. Dr. Kerner's paper is illustrated by six excellent photographs of this picturesque region.

The third of the *Münchener geographische Studien*, edited by Herr Siegmund Günther, consists of a paper on the structure and distribution of earth pyramids and pillars, by Dr. Christian Kittler. The nature of the deposits in which these structures are formed, and of the erosive action which produces them, is discussed in detail. A noteworthy point is the conclusion that the crowning stone is by no means an essential feature.

Dr. Giovanni de Agostini publishes in the *Bollettino* of the Italian Geographical Society a preliminary note on some results of exploration of the lakes of the Roman province. Soundings and temperature observations at various depths, made during 1896 and 1897 in the lakes Bolsena, Mezzano, Vico, Monterosi, Bracciano, Martignano, Albano, and Nemi, are discussed, and contour maps are appended.

At the meeting of the Vienna Academy of Sciences on February 10, the President read a letter from Prof. J. Luksch, of the *Pola* expedition, dated from Suakim on January 23. On January 10 the *Pola* anchored at Ras Tarfu, and a boat was sent to Geishan to obtain a pilot for El Wasm and Kunfida. Next day a party was landed to make observations, but the observers were attacked by Bedouins, and only escaped after some sharp fighting under cover of the guns of the ship. Fortunately there was no loss in killed or wounded; even the instruments were brought off safely. Since leaving Mocha, the *Pola* has made valuable observations, chiefly geological, at a number of points along the coast, and amongst the islands.

AN instance of the service which the Department of Scientific and Technical Research of the Imperial Institute is able to render appears in the number of the *British Central Africa Gazette*, which has just reached this country. A specimen of limestone found on Kilwa Island, Lake Shirwa, was sent to the Institute for an opinion as to its value, and Mr. Wyndham R. Dunstan sent the following report upon it:—"The sample of limestone from Kilwa Island, which is used at Zomba for making lime, turns out to be calcium carbonate—Iceland spar. It contains small quantities of iron and magnesium, and also of phosphate. This last constituent, though minute (0·1 per cent.), should be borne in mind in connection with the possible use of the mineral, either burnt or in its natural state, as a manure. Another point, to which I think it would be well to direct attention, is the value of large, well-formed, colourless *transparent*, rhombohedral masses of the spar. These are employed in the construction of certain optical instruments, and I was informed by one of the principal manufacturers not long ago that the supply of these crystals is now very scarce." The *Gazette* states that, on receipt of this information, the Acting Commissioner took steps to procure and send home for valuation transparent specimens of this crystal.

IN a presidential address to the Conchological Society, published in the January number of the *Journal of Conchology*, Prof. Hickson offers a suggestion to explain the untwisting of the body which has admittedly taken place in certain groups of Gastropod Mollusca. The asymmetry of the Gastropod body was clearly brought about by the acquisition of a spire-like shell, into which its possessor could completely withdraw. Such a shell, however, though advantageous as a protection, is an obstacle to locomotion; therefore, if the Gastropod body could be protected in another way, the *raison d'être* for a spiral shell would disappear. Any increase in the size of the foot, bringing about increased powers of locomotion, would be an advantage to the species in giving it a wider range; and, to obviate the disadvantage of exposing the body to the possible attacks of enemies, an obnoxious or poisonous fluid might be secreted. In support of this view, Prof. Hickson states that among Opisthobranchs there is actually a series of forms showing a gradual diminution in the twist of the shell and a corresponding increase in the size of the foot; and, in addition, points out that some Nudibranchs have been shown to be distasteful to fishes.

IN *Bulletin* 11, new series, of the U.S. Department of Agriculture (Division of Entomology), Mr. L. O. Howard describes the introduction and spread of the Gipsy Moth (*Porthetria dispar, L.*) in Massachusetts, and the means employed for its extermination. This species, injurious on the Continent, but now apparently extinct in Great Britain, was introduced into Massachusetts in 1869 by the escape of examples imported for experiments in silk-growing. Becoming acclimatised in scrub-undergrowth, it multiplied slowly in spite of efforts made to check it, becoming a serious pest by 1889. Since that time its range has extended to about 220 square miles, within which area it has done enormous destruction by the defoliation of deciduous trees. The State has fought it energetically, expending in the the last eight years as much as 725,000 dollars, in addition to 40,000 dollars allowed by Congress. In some years, however, the grants have been made too late to allow the work of destruction to be adequately proceeded with. The chief measures relied on are spraying the foliage with lead arsenate, destruction of the eggs with creosote, grease-banding the trunks to prevent caterpillar ascent, or tying them round with strips of coarse canvas (burlap), under which the caterpillars assemble, and whence they can be collected. Mr. Howard, who claims that this will rank as "one of the great experiments in economic entomology in the history of the world," estimates that more than nine tenths of the colonies, large and small, existing in 1891, have been exterminated; and, except for the difficulty of dealing with woodlands, there appears to be no reason why continuance of the present treatment should not ultimately achieve the total extirpation of the insect.

PROF. PUTNAM has called our attention to an error in the summary of his paper on the magnetic survey of Greenland (NATURE, February 10, p. 347). He points out that the balancing ring employed was of appreciable width, and that, therefore, the formula used in computing the moment of inertia was correct. In this Prof. Putnam is quite right, and the writer of the notice regrets that he did not follow the description of the instrument with sufficient care. As stated in the article, the numerical results are in no way affected.

A NEW periodical—*The Wide World Magazine*—has just been commenced by Messrs. Geo. Newnes, Ltd. The first number contains several instructive articles, all of which are illustrated by striking photographs. Probably no more remarkable collection of pictures have ever appeared than are reproduced in this new magazine. Among the contents we notice a number of pictures of scenes and people in New Guinea, contributed by Prof. A. C. Haddon; photographs of various devotees; an article by Dr. Nansen, entitled "How the North Pole will be reached"; a number of interesting photographs of scenes in China, by Mr. J. Thomson; reproductions of several of Mr. Saville-Kent's curious photographs; and some memories of Navarino, by Admiral Sir Erasmus Ommanney. The magazine is distinctly in advance of the general type of popular periodical, and its contents bear out its motto that "Truth is stranger than fiction."

THE additions to the Zoological Society's Gardens during the past week include a Mexican Deer (*Cariacus mexicanus*, ♂), a Reddish Brocket (*Cariacus rufinus*, ♂), a Globose Curassow (*Crax globicera*, ♀) from British Honduras, presented by H.E. Colonel Wilson, C.M.G.; two Zebus (*Bos indicus*, ♂ ♀) from India, presented by Commander George Stevenson; a Macaque Monkey (*Macacus cynomolgus*, ♀) from India, presented by Mr. M. Lyons; a Senegal Parrot (*Pœocephalus senegalus*) from West Africa, presented by Miss L. Firmin, a Common Fox (*Canis vulpes*, ♂), British, presented by Miss Heard; a Malayan Paradoxure (*Paradoxurus hermaphroditus*) from Singapore, a Hairy Armadillo (*Dasypus villosus*) from La Plata, a Grand Eclectus (*Eclectus roratus*) from Moluccas, deposited; a Manchurian Crane (*Grus joponensis*), four Gold Pheasants (*Thaumalea picta*, ♂ ♂ ♀ ♀) from China, two Argus Pheasants (*Argus giganteus*, ♂ ♀) from Malacca, two Horned Tragopans (*Ceriornis satyra*, ♂ ♀) from South-east Himalayas, two Lineated Pheasants (*Euplocamus lineatus*) from Tenasserim, two Somali Ostriches (*Struthio molybdophanes*, ♂ ♀) from Somali-land, two Many-coloured Parrakeets (*Psophotus multicolor*), four Spotted-sided Finches (*Amadina lathami*) from Australia, a Snow Bunting (*Plectrophanes nivalis*), European; two Lapwings (*Vanellus cristatus*), British, purchased; seven Baer's Ducks (*Fuligula baeri*) from India, received in exchange.

OUR ASTRONOMICAL COLUMN.

MAGNITUDES OF 1081 SOUTHERN STARS.—During a voyage to Australia (1885-86), round the Cape of Good Hope and back by the Red Sea, including a stay of two months in Australia, Mr. Stanley Williams was able to make a very useful catalogue of 1081 stars lying between 30° south declination and the South Pole.

This catalogue has recently been published, so a few words about the method employed in making the observations may be opportune. Before setting out on this journey Mr. Stanley Williams made several hundreds of observations to make himself familiar with this class of work, so that his estimations have considerable weight. He adopted the usual method of making variable star observations by using an opera-glass, and bringing each star and its comparison stars into the centre of the field consecutively. The star undergoing comparison was usually compared with two others of known magnitude, one of which was brighter and the other dimmer than the star to be observed. Instead, however, of estimating the difference of brightness between the comparison star and the star under examination in steps or grades, the magnitude of a step being usually different for nearly every observer, he employed another method. This was to mentally divide the interval between the two comparison stars into as many parts as there were tenths of a magnitude between them, the adopted magnitudes of the comparison stars being, of course, known, and then estimate how many of these tenths the star under observation was dimmer and brighter than the comparison stars.

A step in this case thus corresponded to a tenth of a magnitude on the scale of the "Harvard Photometry." A comparison of the resulting magnitudes of some of the stars observed, which have also appeared in the "Southern Meridian Photometry," shows that "the present catalogue, on the whole, accords exactly with the 'Harvard Photometry,' though the number of stars is too small for absolute certainty." A similar comparison with the "Uranometria Argentina" shows more considerable differences, excepting between 2·8 and 3·4 magnitudes; but it must be remembered that the scale of the "Uranometria Argentina" differs largely from that of the "Harvard Photometry."

In the course of this work one variable, V Puppis, was discovered, and thirteen other stars were found to be probably variable.

The Variables S Cassiopeiæ and S Ursæ Majoris.—Some time ago, in this column (December 2, 1897, p. 105), we had the pleasure of saying a few words about the variable stars S Cephei and T Ursæ Majoris, which Mr. Peek, of the Rousdon Observatory, had so energetically observed and recorded during the years 1887 to 1896. We are now able to refer our readers to another small, valuable pamphlet (No. 3) containing the observations, extending over the same years, of the two variable stars S Cassiopeiæ and S Ursæ Majoris. Each of the observations here recorded is the mean of five visual comparisons with stars whose magnitudes have been previously determined either by Mr. Peek himself or some other observer. Further, the comparisons are all made with stars in the same field of view as the variable under observation, the instrument employed being a 6·4-inch equatorial refractor by Merz. The observations are recorded in a uniform way throughout, in which the date of observation, the magnitude, and remarks as to colour and magnifying power used are given. As in the previous publication, Mr. Peek adds a graphical study of the light changes of these stars throughout each year, and a perusal of these curves is of great interest. We hope Mr. Peek has some more observations of other variables which he will publish in like manner, as it is just such observations that will throw light on the changes which these stars undergo.

Occultations Photographically Observed.—Prof. E. C. Pickering records, in a Circular (No. 26) of the *Harvard College Observatory*, the result of the occultation of 26 Arietis as observed photographically at that observatory. The instrument used was an improved form of that constructed for photographing the eclipses of Jupiter's satellites, and previously described. The phenomenon of this occultation was satisfactorily photographed by Mr. Edward S. King on February 25 of this year. The apparatus was connected with a standard clock, and the photographic plate was moved about 0·03 cm. every time the circuit was closed or opened, two images alternately faint and bright being obtained every second, the duration of exposures being 0·06 and 0·94 seconds. An examination of the series of images showed that the time of occultation could be fixed to within one-tenth of a second. Prof. Pickering adds that by using shorter exposures the uncertainty of the time of disappearance can be still further greatly reduced, especially in the case of brighter stars. 26 Arietis is a star of magnitude 6·1; since satisfactory images were produced in 0·06 seconds, stars probably down to the ninth magnitude can be thus photographically observed. The stellar images were further examined to inquire whether any lunar atmosphere could be detected by noting any change in the intensity of these images; but none was discovered. *A propos* of occultations, it is interesting to draw attention to the fact that Prof. G. P. Bond, more than forty years ago, took a number of photographs of the moon and α Virginis shortly before the occultation of the latter, to determine photographically the position of the moon.

Comet Perrine.—A telegram from Kiel, dated March 21, informs us that the position of Perrine's Comet at 19h. 7m. Mount Hamilton mean time was R.A. 21h 16m., and Declination 26° 44′ north, the movement in these two coordinates being 14 and 37 seconds respectively.

A MAGNETIC STORM.

Since August 1894 no magnetic storm has occurred in England at all equal to one experienced during the last few days. Its first indication at Kew Observatory occurred about 8.55 p.m. on the 14th, when a noticeable increase took place in the horizontal force. This element then oscillated about its normal value to a moderate extent until 4 p.m. on the 15th, when there commenced a large decrease superposed on large oscillatory movements. The minimum was reached about 10.48 p.m. on the 15th. During the subsequent rise, which was very rapid at first, there were some further large oscillations, and the element remained somewhat disturbed until 5 p.m. on the 16th. The vertical force was only slightly disturbed until 2 p.m. on the 15th. After increasing to a maximum about 5 p.m. it decreased rapidly with large oscillations, attaining a minimum about 10.48 p.m. It then reapproached its normal value, the oscillations being large at first, but becoming small early in the morning of the 16th.

The declination disturbance commenced at the same time as that of the horizontal force, but was small until midnight on the 14th. After a general easterly movement, lasting for some hours, the needle reversed its direction, attaining its extreme westerly position about 2·48 p.m. on the 15th. It then recommenced a very conspicuous movement to the east, with various large oscillations. After attaining an extreme easterly position about 11.18 p.m. on the 15th, the needle moved once more to the west, the motion remaining oscillatory. The disturbance did not disappear until about 5 p.m. on the 16th.

The extreme amplitude of the disturbance was: horizontal force, ·0050 C.G.S. units; vertical force, ·0057 C.G.S. units; declination, 1° 26′. In eight minutes, from 10.40 to 10.48 p.m. on the 15th, the horizontal and vertical components exhibited falls of ·002 and ·003 C.G.S. units respectively. The most rapid change of declination occurred some thirty minutes later. Speaking generally, the most salient features were the large falls in both the horizontal and vertical components, and the movement of the declination needle to nearly 1° east of its normal position. The storm was presumably associated with the brilliant aurora visible on the night of the 15th in the northern half of the kingdom and in Denmark (*Daily Weather Report*, March 16).

Charles Chree.

THE AUSTRALASIAN ASSOCIATION.

The meeting of the Australasian Association for the Advancement of Science, held at Sydney in the beginning of January, appears to have been a very successful one. From the reports which came to hand a few days ago it appears that the meeting was attended by the foremost men of science in the various Australasian Colonies, and that a large number of papers were read in the different sections. The Association now numbers more than six hundred members.

The meeting was opened on Friday, January 6, and on the evening of that day Prof. Liversidge delivered his address as president of the Association. Saturday, January 7, and succeeding days in the following week were largely taken up with the sectional meetings. Papers were read in connection with astronomy, mathematics and physics; chemistry, geology and mineralogy, biology, geography, ethnology and anthropology, economic science and agriculture, engineering and architecture, sanitary science and hygiene, mental science and education. Reports of some of these papers appeared in the *Sydney Daily Telegraph*, and from a large number of cuttings which Prof. Liversidge has sent us the following abstracts have been obtained.

PRESIDENT'S ADDRESS.

Prof. A. Liversidge, F.R.S., the Secretary and newly-elected President of the Association, delivered an inaugural address on the evening of January 6. The address was a survey of the objects and work of the Association, and a brief statement of the more important questions with which chemists have lately been concerned. The work of the International Catalogue of Scientific Literature was referred to, and the hope was expressed that Australasia would do something to assist the cataloguing of scientific publications. Reference was made to the fact that the Imperial Institute in London was becoming an institution for the advancement of science. It was now fulfilling its intended objects, and was becoming a most valuable means of disseminating a knowledge of the products and manufactures of the Indian Empire and the Colonies; not only of a commercial, but of a scientific value. Dealing with the chemistry of the ancients, Prof. Liversidge said they might include amongst the recent advancements of science the six important volumes recently published by Prof. Berthelot, of Paris (Perpetual Secretary of the Academy of Science and sometime Minister for Foreign Affairs). Referring to the report of the Committee appointed by the London County Council to inquire into the teaching of chemistry, Prof. Liversidge remarked that Australia at present imported most of its scientific men, but it was time it set about educating its own in greater numbers, and providing greater facilities and better equipped laboratories than the existing ones. The prosperity of a country very largely depended upon the advance of science amongst the people and the more or less practical application they made of each science. Students required to be taught not only the principles of science, but also how to observe, how to use their hands, and to reason and think accurately, and to gather their information from various sources; for there were but few, if any, text-books so well written as to be of equal value in all parts. And especially should they have time and opportunity for some original or research work, in order that they might enlarge the borders of knowledge, and contribute something, however small, to the common stock. Mere training and teaching for a degree was not sufficient; post-graduate work was essential if they wished to turn out scientific men, who would be able to advance Australia by developing its resources and improving the conditions of life. It was not sufficient to merely instruct in the facts and principles of scientific knowledge. It was most important also to impart scientific habits of thought and methods, especially with the object of making new investigations or researches, so that the student might in turn be able to teach something more than he himself was taught or learnt from books. With regard to recent work in chemistry, Prof. Liversidge referred to the discovery of argon and helium, and recent work on the liquefaction of gases. He also made brief references to the manufacture of artificial diamonds and other gems, the diffusion of metals, the phenomena of Röntgen radiation, agricultural chemistry, and other subjects of interest.

ASTRONOMY, MATHEMATICS AND PHYSICS.

Astronomy and Terrestrial Physics.

Mr. P. Baracchi (Government Astronomer of Victoria) selected the subject of "Astronomy and Terrestrial Physics" for his presidential address. He pointed out certain branches of astronomy and terrestrial physics which, in his opinion, had the strongest claim to the immediate consideration of the scientific workers of the Australasian Colonies, and in some cases to the encouragement and support of their Governments. After referring to the present observatories in Australia, Mr. Baracchi said it was very necessary for their observatories to be extremely careful with their available astronomical energy in order to turn it to the best possible account, and it should be employed solely in the preparation of data, which were demanded of them, as the most valuable contribution they could give to astronomy at the close of the present and commencement of the next century. Sidereal astronomy was well advanced in the Southern Hemisphere; indeed, it was said ten years ago that they were ahead of the Northern Hemisphere in point of exact star catalogues. In all other respects, however, their knowledge of the Southern Hemisphere was deficient. The course before them was clear. Celestial photography, astronomy of position, and fundamental investigations for the improvement of both these branches should be the chief objects of their endeavours in the present and immediate future. Other branches of astronomical research must be left, and recommended to the amateur astronomers of the Colonies. The best service that could be rendered to astronomy by the amateurs would be to direct their efforts to a class or classes of observations which could not be made by observers in the Northern Hemisphere. With regard to terrestrial physics, there were certain subjects which derived their great importance not only from purely scientific considerations, but from their more or less direct bearing upon material interests, from the fact that in very recent years and at the present time they had been taken up with renewed vigour and determination in the hope of improving our knowledge on many points which still remained unexplained. Prominent amongst these was terrestrial magnetism, from a knowledge of which it was hoped would be gained a solution of some of the riddles which were now unexplained. It was recognised that the main question to which future efforts should be directed was to expand and coordinate magnetic work done all over the world for obtaining a more correct and complete knowledge of the distribution of terrestrial magnetism and of its variations. The establishment of an observatory in the interests of this science was a duty which New Zealand owed to the scientific world.

Cloud Heights and Velocity

A paper on "The Measurement of Cloud Heights and Velocity" was read by Mr. P. Baracchi. The year 1897 had been called by some writers on meteorological subjects "the cloud year," on account of the systematic observations of clouds which were carried on in nearly all the civilised countries during that period under a scheme laid out and finally agreed upon in all its detail by the International Meteorological Committee at its Upsala meeting in 1894. The object of the scheme was to obtain more uniform and comprehensive data to serve as the basis for the further study of atmospheric conditions, as indicated by the forms and movements of clouds. After a brief reference to the methods adopted in Victoria for securing results anticipated by the scheme, Mr. Baracchi said there were now some 20,000 observations ready. For the determination of absolute height and velocity a pair of stations for simultaneous observations were established, one being on the grounds of the Melbourne Observatory and the other on the roof of Parliament House at a distance of 6820 feet bearing. After consideration he adopted the photographic method, which had been successfully employed at the Kew Observatory some years ago. The absolute height and velocity of a cloud could, provided it was suitably situated, be determined from two photographs of it taken simultaneously with two cameras placed at a distance of from a few hundred yards to one or two miles from each other, the cameras being in all respects equal and rigidly mounted, so as to point accurately to their respective zenith, namely, having their collimation axes truly vertical. Under good conditions the highest clouds could be measured within 500 feet and the lower within 50 feet.

The Source of Periodic Waves.

Mr. H. C. Russell, F.R.S., Government Astronomer of New South Wales, read a paper on "The Source of the Periodic Waves, sometimes called Earthquake Waves, which reach Sydney from time to time." He stated that these waves were recorded very frequently in Sydney, and had the same period as the waves known to be caused by earthquakes—that was about twenty-six minutes from crest to crest; but it was shown that only about 1 per cent of them originated in earth movements; and that 60 per cent originated in Bass' Straits, when the meteorological condition known as a low pressure arrived at that part of Australia. The effect of low barometers was to cause a rise in the sea level, to provide for which currents set in along the south and east coasts of Australia, which, meeting in Bass' Straits, produced waves, and set them going in Tasman Sea, whence they were recorded on the Sydney and Newcastle tide gauges. It was also shown that at least another 10 per cent. of these waves originated in Tasman Sea by the action of heavy gales. That was, in all, 70 per cent. of the periodic waves originated from meteorological disturbances, and probably the remainder were due to these causes, although the connection had not yet been actually traced. Reference was made to Lake George, where somewhat similar periodic waves were frequent, and all were traced to meteorological causes.

Seismological Report.

In presenting the report of the Seismological Committee, the Secretary, Mr. George Hogben, of Timaru, New Zealand, referred to the work already done in his own Colony through the officers of the Telegraph Department, who, on the occurrence of any earthquake shock, filled up certain forms, stating the exact time and duration and such other details of the earthquake as might enable the seismologist to determine the origin of the disturbance, the velocity with which the waves were propagated through the earth's crust, and sometimes to make a very good guess as to the nature of the subterranean causes that gave rise to the earthquake. By means of these observations the sources of many of the earthquakes had been accurately found, their velocity of propagation determined, as in general rather under twenty miles a minute; in a few cases the depth of the origin was also ascertained, the deepest one found so far coming from a point about twenty-four miles below the earth's surface. This work had been done in New Zealand since 1889, and the other Colonies had been asked to follow suit. This they had done to a certain extent, but the Committee was anxious that the system should be developed, and made uniform throughout. Of recent work the most interesting item was probably the fact, based upon rough calculations from returns sent by Sir Charles Todd, and others, that the great South Australian earthquake of May 10, 1897, proceeded from a line parallel to the coast near Beachport and Kingston, and was possibly due to a sliding of one part of the crust upon another, such as forms what was called in geology a "fault." This was probably deep, but the later and slighter shocks were surface ones, caused by readjustments of the immediate crust. The subject was still under investigation by the Secretary. But Mr. Hogben pointed out that it was as part of a world-system of seismological observations that the work of the Committee might be most useful. An International Seismological Committee had been set up embracing all the ablest workers in every part of the world, and in co-operation with that Committee were Committees of the British Association and of the Royal Society. They desire especially to be able to track the microseismic vibrations of minute earthquake waves, which travelled from the sources of disturbance all round the earth's surface, or it might be right through the solid mass of our world (if it was solid). The speed of these finer waves was many times greater than that of the larger waves felt by us, reaching a velocity as great as twelve miles per second, or even more. For the purpose of observing them the International Committee had agreed upon a certain type of instrument, the horizontal pendulum to be used by all stations alike, as it was important that instruments of the same kind and of the same degree of sensitiveness should be employed for purposes of comparison.

Mr. Hogben stated in answer to questions that, at the suggestion of Sir James Hector, the New Zealand Government had ordered two instruments—improved forms of the horizontal pendulum. He asked for the moral and financial support of the Association in this object. Unless instruments were procured at once for Sydney, Melbourne and Timaru (the three stations in Australasia named by the International Committee), the chain of world-stations would be interrupted.

CHEMISTRY.

Constitution of the Matter in the Universe.

The New South Wales Government Analyst, Mr. William M. Hamlet, delivered the presidential address in this section, the subject being "The molecular mechanism of an electrolyte." He defined an electrolyte as a body in solution or state of fusion, capable of being instantaneously decomposed by a current of electricity, and he claimed that if the explanation he offered was adequate for the electrolyte, it must hold good for the constitution of the matter in the universe, so that the treatise on the electrolyte has a most important scientific bearing. The method of investigating the action of one body upon another, he reminded his audience, was brought to a high degree of accuracy by the immortal work of Sir Isaac Newton. He alluded to some observations of the late Prof. Clifford, made over twenty years ago, this authority remarking, almost prophetically, "We can look forward to the time when the structure and motions in the inside of a molecule will be so well known that some future Kant or Laplace will be able to make an hypothesis about the history and formation of matter."

Red Rain Dust.

Much interest was manifested in a paper read by Mr. Thomas Steel on "Red Rain Dust," in the section devoted to chemistry and chemical research. The author remarked that from time to time records of the fall of dust, either alone or accompanied by rain, have been reported from various parts of the Australian Colonies, in common with the rest of the world. Although it was extremely probable that in the great bulk of the cases the dust was merely of terrestrial origin, it was interesting when positive facts regarding the source of the material could be ascertained. On December 27, 1896, an unusually heavy fall of dust of a red colour occurred in Melbourne and was carried down by rain.

An analysis of a clean sample of this dust gave the following results:—Organic matter, 10·70; sand, insoluble and undetermined, 66·21; soluble silica, ·75; ferric oxide, 4·68; ferrous oxide, ·50; alumina, 15·16; lime, 1·36; sulphuric anhydride, ·62. The dust may therefore be regarded as a characteristic example of ordinary surface soil, such as is derived from the weathering of volcanic rocks. Both in appearance and composition it agreed closely with several samples of such soil from widely separated localities. Under the microscope, in addition to the diatoms noticed by other observers, the dust was seen to contain a few lepidopterous scales.

GEOLOGY AND METEOROLOGY.

Early Life on the Earth.

In this section the President, Prof. F. W. Hutton, F.R.S., delivered an address on the subject of "Early Life on the Earth." After describing the various periods through which the earth has passed, Prof. Hutton presented some speculations regarding pre-Ordovician life. Speaking of the origin of life, he said it was highly probable that the first living organisms were evolved near the surface of a warm ocean. They might safely assume that the first protoplasm was not so complicated a substance as it had since become. Ordovician and Silurian life followed, and the lecturer said, in conclusion: "We have thus arrived at the conclusion that the ocean was the mother of life; that on its surface floated the first organisms whose descendants, but little changed during all the millions of years that have since passed away, still float and multiply. Presently some of these animals found their way down to the bottom, where all the débris from the floating organisms collected, and here in still water they lived and increased for a long time. Slowly they invaded the rough waters of the coastline, and at last gained a footing on the land. It was plants which formed the army of invasion that conquered the land."

Coral-boring Expedition to the South Seas.

Considerable interest was manifested in the section devoted to geology and mineralogy, owing to the fact that Prof. David was announced to read a paper on "The Coral-boring Expedition of 1897 to the Island of Funafuti in the South Seas." The funds for the expedition were found chiefly by Miss E. Walker, of Yaralla, the late Mr. Ralph Abercrombie, and the Royal Society of London, while the New South Wales Government lent a diamond drill and the workmen. The method of working the drill and simultaneously attacking the great coral cliff which bounds the atoll seawards was explained, and an account given of some of the manners and customs of the natives. Special reference was made to the nature of the last part of the boring done while Mr. Sweet was in charge. The last 30 feet of core were particularly interesting, being formed of a soft chalky rock, with numerous foraminifera, and showing that the coral formation proper had been all but completely penetrated. Had it been possible to bore a little deeper, Prof. David thinks that the foundation rock would have been reached. Mr. Sweet had done all that he judged would most conduce to attaining this end, and when the boring had to be stopped had left the bore in such a condition that it was possible in resuming the bore to utilise the old borehole, now 698 feet deep. Prof. David urged that this meeting might use its influence with the Council of the Association to have a recommendation made to the Government of New South Wales to extend the loan of the diamond drill so as to admit of the boring being continued till bedrock was reached. A letter received from the Royal Society of London, stated that the Society was so pleased with the results already attained at the Funafuti bore, that it had voted a further sum to meet the expenses, making their total subscription up to the present 500*l.* Opinions amongst scientific men in Great Britain as to the conclusions to be drawn from the evidence of the Funafuti bore were at present divided. While the advocates of the Darwinian theory were inclined to congratulate themselves upon the results, Dr. Murray's supporters say that the evidence substantiates their views. Prof. David considered that the last portion of the core obtained weakened the subsidence theory.

Glacial Research.

The report of the Glacial Research Committee, South Australia, was submitted by Prof. T. W. E. David and Mr. Walter Howchin. The localities dealt with were comprised within the peninsula which formed the southern limits of the Mount Lofty Range. In 1859 Mr. Alfred Selwyn, at that time Government Geologist of Victoria, whilst travelling through the Inman Valley, discovered a polished rock surface which, to the practised eye, exhibited clear proof of glacial action. This was the earliest discovery of its kind in Australia, but the position was lost sight of until re-discovered by the authors of the paper in March last. This polished pavement, which measured over 20 feet in length and 6 feet in breadth, occurred in the bed of the Inman River, a little past the seventh mile-post from Port Victor. The glacial beds of the Inman River have at present an elevation of over 600 feet above sea level. If, therefore, the agency of shore-ice as the means of distribution were admitted they must assume that there had been an elevation of the land since the days of glaciation. The facts were, perhaps, best explained by a reference to a combination of agencies, rather than to a single form of ice action.

A paper "On the Occurrence of Glacial Boulders at Yellow Cliff, Crown Point Station, Fincke Valley, Central Australia," dealt with a recent discovery by Prof. Baldwin Spencer, of Melbourne University, and Mr. P. M. Byrne, of Alice Springs telegraph station, of large glaciated pebbles at a level of about 1000 feet above the sea. This is the nearest point to the tropics in Australia at which traces of glacial action have been observed, and the discovery is therefore of great interest. The pebbles are from 2 inches up to 1 foot in diameter, and form a layer about 3 feet in thickness, overlying a soft grey sandstone, the geological age of which is unknown. It is not known at what period of geological time the ice existed which produced these markings. The only other instance of possible evidence of ice action in Australia near to the equator than Yellow Cliff is that mentioned by Mr. R. L. Jack, viz. the Bowen River coalfield of Queensland. At that locality small boulders of rock foreign to the district are found embedded in the marine permo-carboniferous strata. It is just possible that these boulders were rafted to their present resting-place by floating trees, but the glacial explanation is thought to be the more probable one.

A paper entitled "Further Evidence of Glacial Action in the Bacchus Marsh District," by C. C. Brittlebank, G. Sweet, and Prof. David, dealt specially with the deep preglacial valleys bounded by steep sides, 500 to 600 feet high, which had been choked with glacial drift, and powerfully glaciated at their bottoms and sides, as well as on the summits of the intervening ridges. The fact was commented on that very few rocks of local origin were observable in the glacial beds, and that all the glacial beds were more or less stratified, in which respect they differed markedly from the glacial till of Northern Europe.

Geology and Mineral Deposits of Portions of West Australia.

The New South Wales Government Geologist (Mr. E. L. Pittman), read a paper "On the Geology and Mineral Deposits of certain portions of West Australia." The geology of the Perth artesian water basin was first dealt with, and it was stated that the water occurred in a porous rock, consisting of calcareous sandstone of æolian origin. The basin was about fifteen miles wide, but extended along the coast for several hundred miles in a north and south direction. The chief peculiarity of this artesian basin was that it was not covered by any continuous impervious beds, such as had hitherto been regarded as essential for the occurrence of artesian water. Reference was next made to the Collie coalfield, and the opinion was expressed by the author that it was of Mesozoic age, like the Victorian coalfields, and that of the Clarence River. The Coolgardie goldfield was then briefly alluded to. The gold here occurred in some of the reefs in phenomenally rich "chutes," separated by intervals of barren material. The "cement deposits" of the 25-Mile were described as alluvial deposits, containing very angular gold, in fairly-defined channels. The Kalgoorlie goldfield was described at considerable length, and particular reference was made to the famous telluride deposits of the Boulder. These, in Mr. Pittman's opinion, consisted of igneous dykes of quartz, felspar, porphyry, which had been subjected to an enormous amount of crushing, and this had induced a schistose or foliated structure in them.

General Geology.

The Rev. J. Milne Curran read a paper on "Artesian Water in New South Wales." He concluded that the artesian water of the north-west and west of New South Wales was derived from Triassic beds, and, in his opinion, there was no evidence to show that a single artesian well in the Colony derived its waters from Cretaceous rocks. Photographs were exhibited of artesian flows, Cretaceous and Silurian country in the far west.

In the discussion that followed, Mr. R. L. Jack stated that artesian water had just been struck in Queensland, on the central line of railway at Maria Creek, west of the Dawson River, in rocks of permo-carboniferous age. These were the oldest rocks in Australia in which artesian water has as yet been discovered, and they were not known previously to be water-bearing.

The Rev. J. Milne Curran, in laying before members of the section some "Notes of a Geological Reconnaissance on the Mount Kosciusko Plateau," said that his conclusions were (1) that there was no satisfactory evidence of extensive glaciers having existed in the present valleys, under the highest peaks of Mount Kosciusko; (2) that there was no evidence of extensive glaciation on the Kosciusko plateau; (3) that the "glacial epoch of Australia" in post-Tertiary times, as described by Dr. Lendenfeld, had no foundation in fact.

BIOLOGY.

Relations of Morphology and Physiology.

The President of this section, Prof. C. J. Martin, dealt, in his opening address, with the growth of the science of morphology, which was now a separate science from physiology; the scope of research in both directions having, within the last fifty years, become greatly widened. Morphology deals with the structural conformation and anatomy of animals; physiology, with the functional workings of the animal system. During the last half-century the discoveries in both these sister sciences have been of a most beneficial character to mankind, and the future was full of possibilities. Prof. Martin did not let the occasion pass without bearing testimony to the ungrudging and valuable services of the late Prof. Jeffery Parker, during his term of the presidency of the section.

GEOGRAPHY.

Submarine Geography.

The President, Sir James Hector, K.C.M.G., F.R.S., in his presidential address, dealt at length with the subject of "Submarine Geography." Since their last meeting, Sir James said, the results of the exploring expeditions equipped by the munificence of the late Sir Thomas Elder and Mr. Horn had been made public, and the wonderful expansion of our knowledge of the central and western parts of the continent obtained through the intrepid journeys would greatly assist the material development of the vastly rich but hitherto neglected interior area of Westralia. Another feature of great promise to the future advance of geographical discovery in the more difficult parts of the Australian continent was the steady extension of the "artesian well" system into the arid areas of the interior, where the absence of water had not only prevented the settlement of the country, but even its exploration, and had caused the loss of many brave and enthusiastic pioneers under circumstances of intense personal suffering. When the sources of underground water circulation were fully comprehended and utilised, both exploration and occupation of large and almost unknown areas would become possible. After dealing with geographical researches conducted in different parts of the world, the President said the crowning event that had absorbed the interest of geographers since the last meeting was the successful achievement of Nansen. The scientific results of this wonderful venture had not yet been published, but two remarkable advances in geographical science were announced: (1) that the North Polar Ocean was not a shallow sea, with scattered islands, distributing icebergs, but a profound ocean basin; (2) that there were definite movements of the great ice cakes, and that they crossed, and did not merely circulate round the pole.

Antarctica.

"Antarctica" was the subject of a lecture delivered by Sir James Hector, the president of the geographical section. The Antarctic Continent, or Antarctica, as it had been recently called, was an immense area of about 4,000,000 square miles; but they knew very little about it. There had been a number of expeditions to the North Pole, but very little had been done in the way of obtaining knowledge with regard to the South Pole. The last expedition by Nansen had proved that the North Polar region was a great cavity, nearly two miles deep, instead of being, as hitherto supposed, an island with half-open seas. The Antarctic regions, on the other hand, consisted of a great solid mass of land, extending far beyond the area explored by Nansen at the North Pole. Captain Cook, in 1776, furnished the first information with regard to the Antarctic regions; but it was not until Ross' expedition in 1841, followed by the *Challenger* in 1874, that any accurate information was obtained in regard to this continent. By means of his sounding apparatus, Ross made the discovery that there was a belt of water two miles in depth right round the Antarctic regions. In some places it showed a depth of 2000 fathoms, and in other places 4000 fathoms, without any bottom. Ross discovered Victoria Land, a mountain promontory stretching for 500 miles north and south, during which he passed through a belt of ice over 100 miles in width into calm, beautiful water beyond. Ross sailed south to latitude 78°, where he found volcanic mountains from 12,000 to 15,000 feet high, towering above a vast range of snowy mountains, and vomiting forth flames and lava. Huge glaciers descended for miles into the sea; but along the rocky shore no landing-place could be found, there being no harbour or indentation of any kind. A landing was, however, effected on Possession Island, which lay a short distance off the mainland. He attempted to reach the mainland from this island, but failed, and, turning eastward, he found a perpendicular wall of ice 200 feet high, and he traced it for 300 miles without a break. On some days the sun shone out with great brilliancy from a perfectly serene and clear sky of intense blue. Reference was made to the atmospheric conditions and currents of the Antarctic region, and then Sir James pointed out that within this circle no living thing had yet been found which belonged to the land. The life-history of the birds was most remarkable, because they could not breed within the Antarctic circle owing to there being no place for them to build their nests, except ice that was melting. In concluding, Sir James expressed the hope that the exploration of Antarctica would be continued. One of the most important things to be done in this direction was to settle the exact position and intensity of the magnetic pole, especially in the interests of navigation. Until they had established by survey the magnetic conditions of the southern end of the globe, careful and scientific provision could not be made for the safety of iron ships steaming upon different courses.

Australian Oceanography.

"A Contribution to Australian Oceanography" was the title of a paper by Mr. T. W. Fowler. The paper was suggested by the reports of the *Challenger* expedition, which seemed to leave room for much further investigation. An attempt had been made by the writer to get additional information, and with this end in view he had obtained from the captains or officers of various intercolonial steamships proceeding at regular intervals, samples of water passed through by them, together with the temperature of the sea at the time the sample was obtained. The samples were taken as near the vessels' bows as possible, and placed in well-cleaned bottles, which were tightly corked and forwarded to Mr. Walker for examination at the Melbourne University. Mr. Buchanan's method of conducting the examination was adopted. Two hydrometers were used, and the results were checked by testing the instruments in solutions of known densities. Tables were given showing the densities of waters obtained between Fremantle and Melbourne; between Melbourne and Brisbane; on the east coast of Australia generally; between Melbourne and the Bluff; on the Sorrento Back Beach, Bass Strait, and a number of other places.

Remarks on Central Australia.

"Notwithstanding the labours of the past, the last volume of Australian discovery is still incomplete," was the opening remark of the paper by Mr. W. H. Tietkins, who in 1889 led an expedition, which was fitted out under the auspices of the South Australian branch of the Royal Geographical Society, one of the objects of which was to determine the outline of Lake Asmodeus in Central Australia. Mr. Tietkins suggested that attention should be directed to the Rawlinson and Peterman Ranges, which lie to the north of the Mann and Tomkinson Ranges, and which were bounded on all sides by barren and inhospitable sandy wastes. To the best of his belief these ranges had not been visited, except by Giles, whose party was much reduced. These ranges formed an extensive and fertile field for systematic and scientific examination. It was suggested that a party might leave the settlements at Giles Range or Erldunda, and proceed from there to Mount Olga, where the first depôt would be formed, pending the discovery of suitable water being found further west and nearer the scene of operations. No difficulty would be experienced in reaching Sladen Water. It might be almost taken for granted that valuable waters would be found before reaching so far west. From the western end of the Rawlinson Range the party could return by a slightly different route, and if time and circumstances allowed before leaving Sladen Water. The conviction was forced upon him that no pasture lands of sufficient extent might be looked for that would develop the western interior, but the hope might reasonably be entertained that the mining industry in that latitude would challenge the enterprise of the Australian people.

ETHNOLOGY AND ANTHROPOLOGY.

The Origin of the Aborigines of Tasmania and Australia.

This was the subject chosen by Mr. A. W. Howitt, President of the ethnological and anthropological section, for his presidential address. He was of opinion that, in spite of the contention of many writers to the effect that the primitive Australians and Tasmanians had come from other lands in ships or canoes, there were but little evidences to show that they had any knowledge of navigation or of sea-going vessels. In any solution of the origin of the natives of Australia one fundamental element must be that the ancestors of these savages reached Australia or Tasmania by land; or if the land connection was not continuous, the intervening channels were such as could be traversed by vessels no better than the catamarans or canoes above mentioned. The lecturer quoted many geological facts, all of which tended to show that an immense period of time was one of the elements of any solution of the problem, and that during that period the Australians had been isolated from outside influence, having at the same time a continental area in which to develop their institutions. The level of culture of the Tasmanian had been termed the eolithic, and that of the Australians might fairly be termed neolithic, or even as regards some of the tribes of Central Australia bordering on the palæolithic. The social organisation of the Tasmanians was also below the level of that of the Australians. Finally he came to the conclusion that the Australians reached the continent by a land bridge connecting with the Indo-Asiatic continent or by a land extension of the Austral continents to the north-west or over some shallow channels separating Australia from these lands.

A lecture on "Native Life in Central Australia" was delivered by Prof. W. Baldwin Spencer. After describing the difficulties of travelling, the lecturer remarked that the country was divided into the lower steppes, the desert country, and the higher steppes, where the James and Macdonell Ranges rear their lofty summits sometimes to a height of 5000 feet. Lake Amadeus in the dry season is a mere sheet of salt. Ayers Rock, another remarkable formation of this distant and mysterious land, rises abruptly from the surface of the desert country. It is about one mile long and five miles in circumference. Formerly there were vast rivers here, and animals, such as the diprotodoton, a wombat-like creature about four times as large as a kangaroo, flourished on the plains. Now animal life was scarcely noticeable. The fish lived in the waterholes in the hills until the wet season came and washed them down the foaming gorges of the mountain to the lower lands. In the dry season the water-frog fills himself up with water, and, rolling himself into the mud, exists there until the next rains, which may not come for two years. In the meantime the frog may have the misfortune to provide a drink for a thirsty native. The natives also obtain water from the roots of trees. They all believed that each one was under the ægis of the spirit of some animal or plant, which they revered almost as gods. In connection with the tokens, they held all sorts of weird ceremonies, bedecking themselves with great elaborateness, and going through all sorts of antics, such as imitating frogs, emus, kangaroos, or whatever it was they held in veneration. Group marriage prevails; that is, men in one group can only marry the women in another single group. The Engwurra, or the fire ceremony, through which a youth has to pass before being entitled to be considered a man, seems to be peculiarly exacting to the candidate for manhood.

RESOLUTIONS OF COUNCIL.

At the final meeting of the General Council on January 13, the following suggestions from the Recommendation Committee were agreed to:—(1) That the New South Wales Government acquire the quarry of prismatic sandstone at Bondi, with a view to its preservation as a remarkable geological occurrence. (2) The re-appointment of the Committee on "The Systematic Conduct of the Photographic Work of Geological Surveys." (3) The appointment of a Seismological Committee for 1900. The Government of New Zealand to equip Timaru with approved seismological instruments, in charge of Mr. George Hogben. A contribution of 25*l.* was voted towards the preceding object. (4) The appointment of a Committee to secure magnetic surveys at the extreme south of New Zealand. (5) Expressing the opinion that the publication of Victorian continuous magnetic records is desirable. (6) That the Committee be re-appointed to continue the investigation of the mineral waters of Australasia. (7) That the New South Wales Government be recommended to complete the borings at Funafuti while the bore apparatus remains on the island, and the bore remains open. (8) A Committee be appointed to draw up a list of works and papers relating to Australian flora.

The report from the Baron von Mueller Memorial Committee, embodying a resolution, "That the Association places on record its sense of the deep loss sustained by it owing to the death of the late Baron von Mueller, and its high appreciation both of his personal character and the distinguished services rendered by him to science," was adoped.

On the motion of Prof. Kernot, of Melbourne, seconded by Prof. Baldwin Spencer, Mr. R. L. J. Ellery, late Government Astronomer of Victoria, was elected to be President of the Science Congress to be held in Melbourne in the year 1900. Mr. C. R. Blackett, Government Analyst of Victoria, was elected treasurer, and Prof. Baldwin Spencer and Mr. E. F. J. Love were elected joint secretaries for the same Congress. It was decided that the next meeting of the Asssociation after the one to be held in Melbourne will take place at Hobart.

FORTHCOMING BOOKS OF SCIENCE.

IN Messrs. Baillière, Tindall, and Cox's list are to be found:—"A Manual of Surgery," by Drs. William Rose and Albert Carless; "Atlas of Traumatic Fractures and Dislocations," by Prof. H. Helferich (vol. vi. "Hand-Atlas" Series); "English-French and French-English Dictionary of Medical Terms," by H. de Méric, two parts; "Minor Surgery and Bandaging," by Dr. W. G. Spencer, illustrated; "Respiratory Exercises," by Dr. Harry Campbell; "Diagnostic Signs in Women," by Dr. T. W. Eden; "The Clinical Diagnosis of Lameness in the Horse," by W. E. A. Wyman, illustrated; "Practical Toxicology for Physicians and Students," by Prof. Dr. Kobert, translated and edited by Dr. L. H. Friedberg; "Chronic Nasal Obstruction, and Deformities of the Upper Jaw, Teeth, and Palate," by Dr. Mayo Collier; "Atlas of Pathological Anatomy," by Prof. O. Bollinger (vol. vii. "Hand-Atlas" Series), illustrated; "Idiopathic Ulcerative Colitis (Dysentery)," by J. F. Gemmel, illustrated; "Water" (Part ii. of the "Analysis of Food and Drugs"), by T. H. Pearmain and C. G. Moor; and new editions of "A Guide to the Examinations of the Conjoint Board in England and for the Fellowship of the College of Surgeons, with Examination Papers," by F. J. Gant; "Heart Disease, with special reference to Prognosis and Treatment," by Sir William Broadbent, Bart., and Dr. J. F. H. Broadbent; "Diseases of the Throat and Nose," by Lennox Brown, illustrated; "Applied Bacteriology," by T. H. Pearmain and C. G. Moor; "The Practical Guide to the Public Health Acts and Correlated Acts for Officers of Health and Inspectors of Nuisances," by Dr. Thomas Whiteside Hime; "Latin Grammar of Pharmacy," by Joseph Ince; "A Manual of Artistic Anatomy for the Use of Students in Art," by John C. L. Sparkes, with plates; "Handbook for Attendants on the Insane"; "The Register of the Royal College of Veterinary Surgeons."

Messrs. Wm. Blackwood and Sons' list includes:—"A Text-book of Modern Geometry," by J. A. Third; "Lower Geometrical Exercises," by the same author; "Higher Geometrical Exercises," by the same author; "The Elements of Physical Education, a Teacher's Manual," by Dr. David Lennox and Alexander Sturrock, with Original Musical Accompaniments to the Drill by Harry Everitt Loseby, illustrated; "A Manual of Agricultural Botany," from the German of Dr. A. B. Frank, translated by Dr. John W. Paterson, illustrated; and new editions of Sir John Skelton's "The Handbook of Public Health," revised by James Patten MacDougall and Abijah Murray, Part ii. containing other Acts bearing on Public Health, with Notes, Forms, &c.; "Introductory Text-book of Zoology," by Prof. Henry Alleyne Nicholson, F.R.S., and Dr. Alexander Brown, illustrated; "Page's Introductory Text-book of Geology," revised and enlarged by Prof. Lapworth, F.R.S.; "Page's Advanced Text-book of Geology," Descriptive and Industrial, with engravings, and Glossary of Scientific Terms, revised and enlarged by Prof. Lapworth, F.R.S.; "Introductory Text-book of Meteorology," by Dr. Alexander Buchan, illustrated; "Dr. Mackay's Elements of Physiography," illustrated.

Messrs. Bliss, Sands, and Co. announce:—The Progressive Science Series: "Earth Structure," by Prof. Geikie, F.R.S., illustrated; "Volcanoes," by Prof. Bonney, F.R.S., illustrated; "The Groundwork of Science," by Dr. St. George Mivart, F.R.S.; "Vertebrate Palæontology," by Prof. Cope, illustrated; "Science and Ethics," by M. Berthelot; "The Animal Ovum," by F. E. Beddard, F.R.S., illustrated; "The Reproduction of Living Beings: a Comparative Study," by Prof. Marcus Hartog, illustrated; "The Study of Man: an Introduction to Ethnology," by Prof. A. C. Haddon, illustrated; "Man and the Higher Apes," by Dr. Keith, illustrated; "Heredity," by J. Arthur Thomson, illustrated.

Messrs. Burns and Oates, Ltd., promise:—"Genesis and Science," by John Smyth.

The list of the Cambridge University Press includes:—Cambridge Natural Science Manuals, *Biological* Series: "Fossil Plants, a Manual for Students of Botany and Geology," by A. C. Seward; "Vertebrate Palæontology," by A. S. Woodward.

Messrs. Cassell and Co., Ltd., announce:—The "Century Science" Series: "Michael Faraday, his Life and Work," by Prof. Silvanus P. Thompson, F.R.S.; "Cassell's Family Doctor," by a Medical Man; and new editions of "The Story of Our Planet," by Prof. Bonney, F.R.S., with coloured plates and maps, and illustrated: "The Story of Africa and its Explorers," by Dr. Robert Brown, 4 vols., illustrated; "The Countries of the World," by Dr. Robert Brown, vol. v., illustrated.

Messrs. Chapman and Hall, Ltd., will issue:—"Physics, Experimental and Theoretical: an Elementary Treatise Mechanics, Hydrostatics, Pneumatics, Heat and Acoustics," by Dr. R. H. Jude and H. Gossin, illustrated; "The Manufacture of Boots and Shoes," being a modern treatise of all the processes of making and manufacturing footgear, by F. Y. Golding, illustrated; "Notes on Carpentry and Joinery," adapted to the requirements of the City and Guilds of London Institute, the Worshipful Company of Carpenters, and the County Council's Scholarship Examinations, by J. T. Evans: Second Stage, Ordinary or Advanced Course, illustrated; "Chinese Porcelain," by W. E. Gulland, illustrated; "De Pontibus, a Pocket-book for Bridge Engineers," by J. A. L. Waddell; "Machine Design," Part i. "Kinematics of Machinery," by Prof. Forrest R. Jones; "Handbook of Street-Railroad Location," by Prof. John P. Brooks; a new edition of "A Text-Book of Mechanical Engineering." by W. J. Lineham, illustrated.

Messrs. Chatto and Windus promise new editions of: "Flammarion's Popular Astronomy," translated and edited by J. Ellard Gore, illustrated; "Popular Astronomy," by J. Rambosson, translated by C. B. Pitman, illustrated.

Messrs. J. and A. Churchill will publish:—"Manual of General Pathology for Students and Practitioners," by Dr.

Lazarus-Barlow; "Manual of Bacteriology," by Dr. Hewlett; "Manual of Dental Metallurgy," by Ernest A. Smith; and a new edition of "Manual of Dental Anatomy, Human and Comparative," by Charles S. Tomes, F.R.S.

The Clarendon Press will issue:—"Essays on Secondary Education," edited by C. Cookson.

In the announcements of Mr. Clive, of the University Correspondence College Press, we find:—"A Manual of Psychology," by G. F. Stout; "The Tutorial Algebra," by W. Briggs and Prof. G. H. Bryan, F.R.S., Part i., Elementary Course, Part ii. Advanced Course; "Properties of Matter," by E. Catchpool; "Advanced Sound, Advanced Light, First Stage Magnetism and Electricity," by Dr. R. H. Jude; "Advanced Magnetism and Electricity"; "Text-book of Zoology," by A. M. Davies; "Text-book of Botany," by J. M. Lowson; "Advanced Chemistry: First Stage Practical Inorganic Chemistry, Practical Organic Chemistry" by George George; "First Stage Mathematics, Stage ii. Mathematics," by J. H. Grace; "Key to First Stage Mechanics of Solids"; "Coordinate Geometry, Part ii."; "Tutorial Dynamics," by W. Briggs and Prof. G. H. Bryan, F.R.S.; Supplement (on Metals) to Tutorial Chemistry, Part i.. "An Introduction to Carbon Compounds," by Dr. F. Beddow; "Quantitative Analysis, a Sequel to the Analysis of a Simple Salt"; "First Stage Physiology"; "Advanced Physiology"; "First Stage Geology"; "Advanced Geology"; "First Stage General Biology"; "Advanced General Biology"; First Stage Botany"; "Advanced Botany"; "First Stage Agriculture"; "Advanced Agriculture"; "First Stage Hygiene"; "Advanced Hygiene"; and new editions of "Matriculation Mathematics" and "First Stage Mechanics of Fluids."

Messrs. A. Constable and Co. will issue:—Constable's Technical Series: "The Internal Wiring of Buildings," by H. M. Leaf, illustrated; "The Electrical Equipment of Tramways," by H. F. Parshall and Evan Parry, illustrated; "Electro-Metallurgy," by Bertram Blount, illustrated; "Auto-cars and Horseless Carriages," by Dugald Clerk and Worby Beaumont, illustrated; "The Steam Boiler," by H. H. Powles; "The Life of Sir Charles Tilston Bright," by Edward Brailston Bright and Charles Bright, 2 vols., illustrated; "The Simplest Living Things," by Prof. E. Ray Lankester, F.R.S., illustrated; "Electricity in Town and Country Houses," by Percy E. Scrutton, illustrated.

Messrs. J. M Dent and Co. promise:—"With Ski and Sledge over Spitsbergen Glaciers," by Sir William Martin Conway, illustrated.

Messrs. Duckworth and Co.'s list contains:—"Savage Philosophy in Folk-Tale," by Edward Clodd.

Messrs. Friedländer and Sohn (Berlin) will publish:—Britzelmayr's "Zur Hymenomyceten-Kunde," vol. iii. (and last), illustrated; Gerberte's (Papae Silvestri II) "Opera Mathematica," illustrated; A. Bolles Lee's "The Microtomist's Vademecum," German translation, with many additions by the author and Prof. P. Mayer; A. B. Meyer and L. W. Wiglesworth, "The Birds of Celebes and the Neighbouring Island, 2 vols., illustrated; Das Tierreich (the publication of the German Zoological Society), next part, Rothschild's "Paradiseidae"; Trouessart's "Catalogus Mammalium," vol. iv. (and last).

Messrs. Gauthier-Villars et Fils (Paris) announce:—"Eléments de la Théorie des Fonctions elliptiques, by Tannery et Molk," Tome iii.; "Leçons sur la Théorie des marées fluviales et terrestres," by Maurice Lévy.—"Œuvres de Laplace," Tome xii.; "Recueil de données numériques publié par la Société Française de Physique, Optique," by H. Dufet, 1er fascicule; "Œuvres mathématiques de Riemann, traduites," by L. Laugel; "Traité d'algèbre supérieure," by Weber, traduction de Griess; "Leçons nouvelles sur l'analyse infinitésimale et ses applications géométriques," by Méray. Tome iv.; "Distribution de l'énergie par courants polyphasés," by J. Rodet; "Traité pratique de photogravure," by Léon Vidal; "Les Eléments d'une photographie artistique," by Robinson, traduction de H. Colard.

Mr. Heinemann announces:—"A translation of Prof. Müller's work on Krupp's Steel Works," illustrated.

The list of Mr. Hoepli (Milan) contains:—"Coniglicoltura pratica," by Giuseppe Licciardelli, illustrated; "La Sieroterapia," by Dr. E. Rebuschini; "Agronomia e Agricoltura moderna," by Giovanni Soldani; "Astronomia Nautica," by Dr. Giuseppe Naccari; "Luce e raggi Röntgen," by Prof. O. Murani.

Messrs. Hutchinson and Co. promise:—"The Origin and Nature of Man," by Dr. S. B. G. McKinney.

Messrs. Innes and Co. announce:—"Through the High Pyrenees," by Harold Spender and Llewellyn Smith.

Messrs. Lawrence and Bullen, Ltd., will add to their "Angler's Library":—"Salmon and Sea Trout," by Sir Herbert Maxwell; "Trout, Char, &c.," by T. D. Croft.

Mr. H. K. Lewis's list is as follows:—"A Handbook of Diseases of the Nervous System," by Dr C. E. Beevor; "Prof. Furbringer's Diseases of the Kidneys and Genito-Urinary Organs," vol. ii.; "Inflammation of the Bladder," by Dr. Mansell Moullin; "Yellow Fever in the West Indies," by Dr. Izett Anderson; and new editions of Prof. Corfield's "Dwelling Houses; their Sanitary Construction and Arrangements"; Dr. Dudley Buxton's "Anæsthetics"; Dr. Samuel Rideal's "Practical Organic Chemistry."

Messrs. E. and S. Livingstone (Edinburgh) call attention to:—"Practice of Medicine" (Catechism Series), Part iii.; and a new edition of Husband's "Practice of Medicine."

Messrs. Longmans and Co.'s announcements include:—"Essentials of Practical Bacteriology," by Dr. Henry J. Curtis, illustrated; "The Diseases and Injuries of the Lungs and Pleura," by Dr. James Kingston Fowler and Dr. Rickman J. Godlee, illustrated; the Memorial Edition of the late Mr. John Ball's "Alpine Guide," issued by the Alpine Club: vol. i. "The Western Alps," vol. ii. "The Central Alps, North of the Rhone Valley, from the Simplon Pass to the Adige Valley"; "The Training of Young Children," by Ennis Richmond (Mrs. Wilfrid Richmond); "Outlines of Descriptive Psychology: a Text-book of Mental Science for Colleges and Normal Schools," by Prof. George Trumbull Ladd.

Messrs. Sampson Low and Co., Ltd., give notice of:—"Twentieth Century Practice, an International Encyclopædia of Modern Medical Science by Leading Authorities of Europe and America," edited by Dr. Thomas L. Stedman, in 20 vols.: vol. xii. "Mental Diseases, Childhood and Old Age," vol. xiii. "Introduction to Infectious Diseases"; "A Complete System of Nursing," written by various contributors, and edited by Honnor Morten; "Petroleum Motor-cars," translated from the French of Louis Lockert; "Twenty-five Years in British Guiana," by Henry Kirke, illustrated, and a new edition of "The Care of the Sick at Home and in the Hospital," by Dr. Th. Billroth, translated by J. Bentall Endean, illustrated.

Among the announcements of Messrs. Macmillan and Co., Ltd., we notice:—"The Scientific Papers of Thomas Henry Huxley," reprinted from the journals of scientific societies, edited by Profs. Michael Foster and E. Ray Lankester, F.R.S., in four vols., vol. i.; "Essays on Museums and other Subjects connected with Natural History," by Sir William Henry Flower, K.C.B., F.R.S.; "A Text-Book of Botany," by Drs. E. Strasburger, Fritz Noll, H. Schenck, A. F. W. Schimper, translated from the German by Dr. H. C. Porter, illustrated; "A System of Medicine," edited by Prof. Thomas Clifford Allbutt, F.R.S., vol. v.; "Elementary Course of Physics," edited by Rev. J. C. P. Aldous (Britannia Series), in three parts: Part i. Mechanics, Properties of Matter, Hydrostatics, Heat; Part ii. Wave Motion, Sound, Light; Part iii. Magnetism, Electricity; "Elementary General Science," by A. T. Simmons and Lionel M. Jones, illustrated; "Electro-Physiology," by Prof. W. Biedermann, translated by Frances A. Welby, vol. ii.; "Notes on Observations, being an outline of the methods used for determining the meaning and value of quantitative observations and experiments in physics and chemistry, and for reducing the results obtained," by Sydney Lupton; "The Cambridge Natural History," edited by S. F. Harmer and A. E. Shipley, vol. ix. "Birds," by A. H. Evans, illustrated.

Messrs. Methuen and Co. call attention to:—"Three Years in Savage Africa," by Lionel Decle, illustrated; "Exploration and Hunting in Central Africa," by Major A. St. H. Gibbons, illustrated; "The Niger Sources," by Colonel J. Trotter, illustrated.

Mr. Murray promises:—Mr. Arthur Berry's "Manual of Astronomy," illustrated; "Early Chapters in Science," by Mrs. Awdry (wife of the Bishop of Japan); "Five Years in Siam," by H. Warington Smyth.

Messrs. George Newnes, Ltd., will issue:—"The Story of Life in the Seas," by Prof. Sydney J. Hickson, F.R.S., illustrated; "The Story of Photography," by Alfred T. Story; "The Story of Geographical Discovery," by Joseph Jacobs, with maps.

Mr. J. C. Nimmo announces the completion, in parts, of Morris's Works on Natural History.

Messrs. C. Arthur Pearson, Ltd., give notice of:—"Exercise for Health, its Science and Practice," by H. H. Hulbert; "With Peary near the Pole," by E. Astrup.

Mr. Young J. Pentland's list is as follows:—"Diseases of the Heart," by Dr. G. A. Gibson; "Text-book of Medicine," by British authors, edited by Dr. G. A. Gibson; "The Principles of Treatment," by Dr. J. Mitchell Bruce; "Text-book of Physiology," edited by Prof. E. A. Schäfer, F.R.S., vol. ii.; "Renal Growths," by Dr. T. N. Kelynack; "Diabetes Mellitus," by Dr. R. T. Williamson; and a new edition of "Handbook of Obstetric Nursing," by Drs. F. W. N. Haultain and J. Haig Ferguson.

In the announcements of Messrs. Swan Sonnenschein and Co., Ltd., we find:—"The Wonderful Century: its Successes and its Failures," by Dr. Alfred Russel Wallace, F.R.S.; "Aristotle's Psychology," including the Parva Naturalia, translated and edited with commentary and introduction by Prof. William A. Hammond; "Ethics," by Prof. W. Wundt, translated with the author's permission from the second German edition by Prof. E. B. Titchener, vol. iii. "The Principles of Morality and the Sphere of their Validity"; "Physiological Psychology," by Prof. W. Wundt, translated by Prof. E. B. Titchener, two vols., illustrated; "History of Contemporary Philosophy," by Prof. Friedrich Ueberweg, edited by Prof. Max Heinze, translated by Prof. W. A. Hammond (forming a supplement to Erdmann's "History of Philosophy," three vols.); "Student's Text-book of Zoology," by Adam Sedgwick, F.R.S., vol. i. Protozoa to Polyzoa (inclusive), illustrated; "Text-book of Palæontology for Zoological Students," by Theodore T. Groom, illustrated; "Text-book of Embryology: Invertebrates," by Profs. Korschelt and Heider, vol. ii. "Crustacea and Arachnoids," translated by Mrs. Bernard, illustrated; "Practical Plant Physiology," by Prof. W. Detmer, translated by Prof. S. A. Moor; "Elementary Text-book of Botany," based on "A Student's Text-book of Botany," by Prof. Sydney H. Vines, F.R.S., illustrated; "Radiation: an Elementary Treatise on Electro-magnetic Radiation and on Röntgen and Cathode Rays," by H. H. Francis Hyndman, with diagrams; "Pocket Electrical Dictionary: Electrical Words, Terms and Phrases," by Dr. Edwin J. Houston; "Cataphoresis, or Elective Medicamental Diffusion, as applied in Medicine, Surgery and Dentistry," by Dr. William James Morton, illustrated; "Eclipses of the Moon from A.D. 300 to 1900," by Robert Sewell; "Fishes," by the Rev. H. A. Macpherson (Young Collector Series); "Handbook of Grasses," by W. Hutchinson, illustrated (Young Collector Series); "Mammalia," by the Rev. H. A. Macpherson (Young Collector Series); "Birds' Eggs and Nests," by W. C. J. Ruskin Butterfield (Young Collector Series); and a new edition of "Handbook of Practical Botany, for the Botanical Laboratory and Private Student," by Prof. E. Strasburger, edited by Prof. W. Hillhouse, illustrated.

Messrs. Sotheran and Co. will publish, in 12 parts, "A Monograph of the Turdidæ, or Family of Thrushes," by the late Henry Seebohm, illustrated.

Mr. B. G. Teubner (Leipzig) announces:—"Vorlesungen über Geschichte der Mathematik," Moritz Cantor, Dritter (Schlufs-) Band, Dritte Abteilung; "Vorlesungen über Technische Mechanik," A. Föppl, Band III.; "Vorlesungen über Synthetische Geometrie," Jacob Steiner, Zweiter Teil, Dritte Auflage, herausgegeben von Rudolf Sturm; "Das Gesetz der Kleinen Zahlen," Dr. L. von Bortkewitsch; Joh. Kepler's "Weiland Kaiserlichen Mathematikers, Traum oder nachgelassenes Werk über die Astronomie des Mondes," Übersetzt und Kommentiert, Ludwig Günther.

Mr. T. Fisher Unwin promises:—"Through Unknown Tibet," by Captain M. S. Wellby, illustrated; "Across the Sub-Arctics of Canada: 3200 miles by Canoe and Snowshoe through the Barren Lands," by J. W. Tyrrell, with list of plants collected *en route*, a vocabulary of Eskimo words and phrases, and a route map and full classified index, illustrated; "British Guiana; or, Work and Wanderings among the Creoles and Coolies, the Africans and Indians of the Wild Country," by the Rev. I. Crookall, illustrated; *Masters of Medicine*—"William Stokes: his Life and Work (1804-1878)," by his son, William Stokes; "Life of Sir Benjamin C. Brodie," by Timothy Holmes.

Messrs. Whittaker and Co.'s announcements are:—"Alternate Currents in Practice," translated from the French of Loppé and Bouquets by F. J. Moffett: "Electrolytic Methods of Analysis," translated and adapted from the German of Dr. B. Neumann by J. B. C. Kershaw; a volume on "Radiography," by S. Bottone; "A Popular Guide to Commercial Telephony," by M. Byng and F. G. Bell; "Alternating Currents of Electricity, and the Theory of Transformers," by Alfred Still; "Electro-Mechanical Series," adapted from the French by A. G. Elliott: vol. i. "Industrial Chemistry"; "A Text-book of Geography," by Charles Bird; "Electric Wiring Switches and Lamps," by W. Perren Maycock; "Electric Wiring and Fitting Details Book," by the same author.

Messrs. J. Wright and Co. (Bristol) will publish:—"Examination of the Ocular Muscles," by Dr. Ernest E. Maddox, illustrated; "Lectures on Massage and Electricity in the Treatment of Disease (Masso-Electrotherapeutics)," by Drs. Thomas Stretch Dowse and Arthur G. Haydon, illustrated; and a new edition of "Diseases of the Upper Respiratory Tract, the Nose, Pharynx, and Larynx," by Dr. P. Watson Williams, illustrated.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Cambridge.—The Graces for the establishment of Readerships in Surgery and in Geography having passed the Senate, the General Board will proceed to elect the new Readers early in May.

In the House of Lords on Friday the London University Commission Bill was read a third time and passed.

The chair of Veterinary Surgery at the Royal Agricultural College, Cirencester, rendered vacant by the recent resignation of Prof. Wilson, has been accepted by Mr. J. W. Brittlebank.

Mr. J. Montgomery, B.A., Assistant Master at Parmiter's School, and Honorary Secretary of the Assistant Masters' Association, has been appointed Head Master of Uckfield Grammar School, Sussex.

Dr. R. Anschütz, assistant professor of chemistry at Bonn, and Dr. Askenasy, assistant professor of botany at Heidelberg, have been promoted to professorships; Dr. W. J. Simpson, late health officer of Calcutta, has been appointed professor of hygiene in King's College, London; and Dr. H. Ebert, of Kiel, has been appointed professor of physics at Munich.

Sir William Fraser, formerly Deputy-Keeper of the Records of Scotland, who died on March 13, has by his will left to the University of Edinburgh 25,000*l*. for the foundation of a chair to be called the Sir William Fraser Professorship of Ancient History and Palæography, 10,000*l*. for the purpose of the library, and one half of the residue of his estate, which is expected to amount to between 9,000*l*. and 10,000*l*., for general requirements, bursaries, research, publications, &c.

The educational interests of the State of New York are under the general supervision of the Board of Regents of the University, which is appointed by the legislature, and makes an annual report of the general condition of educational institutions throughout the State. It appears from their annual report of the Board, just published, that the first university in the State, in the number of professors and students, and in the amount of endowment, is Columbia University, with 289 instructors and 1921 students in all departments, and an endowment exceeding 17,800,000 dollars in value. Cornell University is a good second in all these particulars; then follow New York University and Syracuse University.

The Duc de Loubat has given to Columbia University a deed of a large block of buildings on Broadway, New York, valued at more than 1,100,000 dollars, and probably worth fully a million and a quarter. The gift is subject to an annuity of 60,000 dollars to the Duke during his lifetime. Upon his death the property or its proceeds, less any excess of income advanced by the University, is to constitute an endowment fund for the support and maintenance of the University library. The fund will be named, in honour of the Duke's parents, the Gaillard-Loubat Endowment Fund. This gift, added to previous endowments, will make the library one of the world's great libraries. The building is the gift of President Seth Low. It now holds 250,000 volumes, and has accommodation for a million. The main reading-rooms seat 400 or 500 readers; and the rooms of the Avery Collection and seminary rooms will accommodate several hundred more. The Duc de Loubat has made many other generous gifts to educational institutions, having founded professorships and scholarships in Berlin, Stockholm, Madrid, and the Universities of France and Italy. In America he has given valuable books and manuscripts to the University of Washington, University of Pennsylvania and Columbia; and at Columbia he founded the Loubat prizes of 1000 and 400 dollars, which are given annually for original work in various branches of science and art.

IN the House of Commons, on Tuesday, Sir John Lubbock called attention to the new Education Code, and the need of extending its provisions so that elementary science might be more widely taught in elementary schools. He moved: "That it is desirable to assimilate the provisions of the English Education Code, as regards class and special subjects, to those in the Scotch Code of 1897." Under the Code the subjects taught in elementary schools fall into three categories—the obligatory subjects, the class subjects, and the so-called specific subjects. The obligatory subjects are, in the case of boys, reading, writing, and arithmetic. The specific subjects comprise various sciences, domestic economy, and one or two languages. With the exception of domestic economy, however, they are not largely taken up. The class subjects are English, geography, elementary science, and history. Sir John Lubbock submitted that all these four subjects are essential. He did not propose to make them obligatory. but thought schools should be encouraged to take them up. So far from this, however, schools are actually precluded from doing so. The Code provides that no child shall be presented in more than two class subjects. If, therefore, a class took geography and elementary science, they must omit history and English. If they took history and English, then elementary science and geography must be omitted. Sir John Lubbock's contention was that this is a radically wrong system of education; that English, geography, elementary science, and history are all important subjects; and that the influence of the Education Department should be exercised not to prevent, but to encourage these being taken up in elementary schools. After a discussion, in the course of which it was pointed out that the whole difficulty is one of time, Sir John Lubbock withdrew his motion.

SCIENTIFIC SERIALS.

American Journal of Science, March.—Geothermal data from deep artesian wells in the Dakotas, by N. H. Darton. Nearly all the waters in the great artesian basin of the Dakotas are perceptibly warm. The author gives a chart showing the distribution of the wells according to temperature, which shows remarkable regional regularities. As regards the cause of the subterranean heat, the suggestion as to the oxidation of pyrites by underground waters is probably untenable on account of the depth. A collection of all available data will be necessary before a theory is attempted.—Examination of some triclinic minerals by means of etching figures, by T. L. Walker. Experiments may be made with etching figures to determine the equivalence of pairs of parallel faces. If parallel faces give different etching figures, the faces do not belong to the same crystal form. This thesis was proved by etching tourmaline with a red-hot mixture of potassium bisulphate and powdered fluorspar, and by etching axinite, cyanite, albite, and other crystals.—Some new Jurassic vertebrates from Wyoming, by W. C. Knight. The new species are called *Ceratodus robustus* and *Ceratodus americanus*.—Auriferous conglomerate of the Transvaal, by G. F. Becker. The workable area of the Witwatersrand is a strip of country a couple of miles in width and about thirty miles in length. The banket skirts the southerly edge of a large area dotted over with proclaimed gold-fields, in which ordinary veins are associated for the most part with crystalline schists. This area includes the northern part of the Transvaal and portions of Mashonaland and Matabeleland. Its extent is approximately 130,000 square miles. The banket is a highly siliceous mass, consisting of quartz pebbles embedded in a matrix composed of sand, pyrite, and other minerals, all cemented by secondary silica. The free gold in the matrix, like the pyrite, occurs in minute crystals or in irregular, sharp-cornered, hackly aggregates. The author inclines to the marine placer origin of the deposit, and believes that until the Lower Cape formation has been traced across the continent of Africa other spots as rich as the Rand may be hoped for.—A spectroscope without prisms or gratings, by A. A. Michelson. A kind of transmission grating may be made of plates of glass a few mm. thick, arranged with their edges in a step-by-step order. The results are comparable with those of the best gratings.

Annalen der Physik und Chemie, No. 1.—Canal rays, by E. Goldstein. The canal rays are so called from the manner of obtaining them by perforating the kathode. They form the yellow layer next the kathode, and when the latter is perforated straight yellow streamers pass through and fill the tube on the side away from the anode. These rays produce no phosphorescence, and are not in themselves deflected by a magnet. They form the prolongation of the kathode rays backwards, and converge when the latter diverge, and *vice versâ*.—Potential gradients in vacuum tubes, by W. P. Graham. The gradient along the tube was investigated chiefly by means of two electrodes mounted on a glass rod a small fixed distance apart. The glass rod was introduced into the tube through the Torricellian mercury column, and could be moved up and down. Maximum and mininum gradients were observed to correspond with the bright and dark strata of the positive light. But such fluctuations were also observed in the dark space itself. Minimum gradients were found to adjoin the two electrodes.—Coloured alkaline haloids, by E. Wiedemann and G. C. Schmidt. The authors endeavour to discriminate between the various theories advanced in explanation of the coloration of alkaline haloids by the kathode rays, and show that it is due not to a physical change, but a slight chemical reduction of the salts.—Determination of relative thermal conductivities by the isothermal method, by W. Voigt. The method devised by de Sénarmont for the investigation of crystalline conductivities may be considerably improved by adding elaidinic acid to the mixture of wax and turpentine. This gives very sharp curves. The method may be extended to the comparison of conductivities of various metals by constructing a rectangle out of two adjacent triangles of the metals in question, and pressing the shorter edge of the better conducting metal against a copper block kept at a constant temperature. The method admits of an accuracy of 2 per cent.—The optical constants of sodium, by P. Drude. The refractive index of sodium, as determined from the reflective properties of the metal contained in a spherical vessel in an atmosphere of hydrogen, is smaller than 0·054, which is the smallest value yet found for any metal. The standard NaK alloy comes next; and then silver with $n = 0{\cdot}18$.—Glow-worm light, by H. Muraoka and M. Kasuya Further experiments show that the photographic effect of glow-worm light is not due entirely to radiation, but partly at least to volatile substances inseparable from animal life. Resin and coffee, and certain metallic oxides, produce a similar effect, even when not in contact with the plate.

SOCIETIES AND ACADEMIES

LONDON.

Royal Society, February 17.—"On the Connection between the Electrical Properties and the Chemical Composition of different kinds of glass." By Prof. Andrew Gray, LL.D., F.R.S., and Prof. J. J. Dobbie, M.A., D.Sc.

In order to finally determine if possible the circumstances which affect the conductivity and specific inductive capacity of glass, several specimens of glass of special composition have been made up for the experimenters by Messrs. Schott and Co., of Jena, and by Messrs. Powell and Sons, of London. It had been previously found, by Prof. T. Gray, that potash and soda lime glasses had a higher conductivity than flint glasses—a result also arrived at by Dr. Hopkinson. Accordingly glasses richer in lead oxide than any formerly available, and in some cases practically free from soda, were made, so as to test whether diminution of the amount of soda and increase of lead oxide would still further diminish the conductivity. Specimens of glass used by Messrs. Schott, mainly in the manufacture of thermometers, were also obtained, as well as of a barium crown glass, not hitherto experimented on.

The conductivities were measured by the direct deflection method by placing the specimen (in some cases the bulb of a long-stemmed flask, filled up to the bottom of the stem with mercury, and immersed in a mercury bath; in others a plate silvered on its two faces) in series with a battery and a very sensitive high resistance galvanometer. The method of loss of charge was tried, but found for various reasons to be less suitable for the comparison immediately in view than that adopted. It is, however, the only method by which, for several of the specimens, results at ordinary temperatures can be obtained. Special care was taken to ensure that no disturbing film of moisture existed on the surface of the glass, and that the conduction was entirely through the plate or the walls of the flask experimented on.

The specific inductive capacities were determined by connecting the condenser formed by the specimen, for about 1/30,000 of a second, with one of Lord Kelvin's air leydens, which had been previously charged, and observing the potential of the leyden before and after the contact.

After the electrical determinations had been made the specimens were very carefully analysed, and the results are given in the paper, which contains, therefore, full information as to the precise composition of the glasses.

The anticipation mentioned above was fully borne out. The specific resistance of the lead potash glasses was for one certainly above $18{,}000 \times 10^{10}$ ohms at 100° C., for another above $35{,}000 \times 10^{10}$ ohms at all temperatures up to 135° C. The specific resistance of the barium glass was also very high; and, what was remarkable in this glass, there was hardly any trace of dielectric polarisation. The authors are pursuing experiments on the electrical and mechanical properties of this glass.

It was found, after the communication of the paper, that the almost complete replacement of the potash in a lead glass by soda diminishes the specific resistance.

The research is being continued with a view to settling a large number of interesting points which have arisen in the course of the work. For this purpose special glasses of as nearly as possible prescribed composition are being made by Messrs. Powell and Sons.

March 3.—"On Apogamy and the Development of Sporangia upon Fern Prothalli." By William H. Lang, M.B., B.Sc.

In this paper the results obtained from a series of cultures of ten species of ferns, the prothalli of which were grown for more than two years, are described. The conditions of cultivation differed from those under which prothalli usually occur in nature, in that fertilisation was prevented by avoiding watering from above; the prothalli were also exposed to direct sunlight. To these causes the results, which in the main agree for the various species, may be ascribed. The most important were the change in form and structure of the prothallus to a fleshy cylindrical process, which sometimes proceeded from the apical region, sometimes from the under surface just behind the latter; the development of conical projections around or in place of archegonia, and the occurrence of more or less numerous cases of apogamy in every one of the species. The latter phenomenon was manifested by the presence of tracheides in the tissue of the prothallus, by the development of isolated members of the sporophyte upon it, and, in every case but one, of complete vegetative buds. On prothalli of *Scolopendrium vulgare* and *Nephrodium dilatatum* sporangia, which sometimes attained almost perfect development, were found. In conclusion the bearing of the results on the nature of the alternation of generations seen in archegoniate plants is considered, and a provisional hypothesis is suggested to explain how the definite alternation of sexual and asexual forms might have originated by modification of individuals of the ancestral algal organisms under the conditions to which they would presumably have been exposed on their assumption of a terrestial mode of life.

"Experimental Observations on the early Degenerative Changes in the Sensory End Organs of Muscles." By F. E. Batten, M.D. Communicated by Prof. Victor Horsley, F.R.S.

The experiments described in the following paper were undertaken in order to show, firstly, that degeneration occurred in the first place in that part of the neuron most remote from the cell, and secondly, to reproduce within the muscle-spindle, if possible, certain changes which had been shown by the author to be present in the case of tabes dorsalis in man.

The results of the research have been to show:

(1) That within the muscle-spindle a spiral form of nerve termination exists surrounding a fine muscular fibre, in the centre of which are large, clear, non-nucleated cells.

(2) That changes take place in the spiral in twenty-four hours after section of the nerve, and that such changes become marked in forty-eight hours.

(3) That degeneration of the medullated sheath of the nerve takes place in the whole course of the nerve at the same time after section of the nerve.

(4) That no fatty change could be demonstrated in the intramuscular cells by the Marchi method similar to those found in the case of tabes dorsalis in man.

Entomological Society, March 2.—Mr. G. H. Verrall, Vice-President, in the chair.—Lord Walsingham exhibited a series of the larger and more striking species of Xyloryctinæ, a subfamily of the Gelechiidæ, especially characteristic of the Australian fauna. The series illustrated the life-histories and the great disparity in colour and form between the sexes of many species. He also gave an account of the family, chiefly from notes by Mr. Dodd (of Queensland), with especial reference to the habits of the larvæ, which live in holes in tree-trunks, to which they drag leaves in the night for the next day's consumption.—Mr. Gahan exhibited a locust, *Acrydium ægyptium* (= *tartaricum*), taken in a house in Hanover Square, and probably imported in vegetables.—Mr. Kirkaldy exhibited species of water-bugs, including *Enicocephalus culicis* and *Gerris robustus*, both taken for the first time in Mexico.—A discussion arose on the reported occurrence of the San José scale, *Aspidiotus perniciosus*, in Great Britain.

Linnean Society, March 3.—Dr. St. George Mivart, F.R.S., Vice-President, in the chair.—Mr. Thomas Christy exhibited specimens of the Mora Nut of British Guiana (*Dimorphandra Mora*, Schomb.), of which some had been lately introduced into London by Colonial brokers as the Kola Nut (*Cola acuminata*). It appeared, however, on analysis, that the former contains no caffeine, a product for which the latter is of definite commercial value. It remained to be ascertained whether the Mora Nut has any economic value.—Prof. W. A. Herdman, F.R.S., read a paper by Mr. F. J. Cole, entitled "Observations on the structure and Morphology of the cranial nerves and lateral sense organs of fishes, with especial reference to the genus *Gadus*." It contains the first description of the lateral-line organs of *Gadus*, and pit-organs were shown to be present. The author concludes that the lateral-line system of fishes was not originally metameric, and that it has nothing to do with the branchial sense-organs. He regards it and the auditory organ as parts of a system, and their nerves (viz. the superficial ophthalmic, buccal, external mandibular, lateralis, and lateral-line nerves), together with the auditory, as of a series *sui generis*, and shows that the so called lateral-line nerve of *Petromyzon* really belongs to the lateralis accessorius system (ramus lateralis trigemini, auct.), the morphology of which he fully describes. The paper deals exhaustively both with the afore-mentioned and the subsidiary branches of the subject, which is treated in detail and historically, with an accompanying exhaustive bibliography.—Prof. Howes, discussing the paper at some length, drew attention to some observations of the Cousins Sarasin, and to the experimental work of Sewall, Steiner, Lee and others upon the auditory apparatus of fishes, which he believed lent support to the author's conclusions.—Mr. G. Claridge Druce read a paper on the occurrence of *Carex helvola*, Blytt, in Britain, in which he gave an account of his discovery of this plant on Ben Lawers, Perthshire, in August 1897. He found it growing in some abundance at an elevation of about 3200 feet. Prof. Blytt and Dr. Christ, to whom specimens had been submitted, both agreed in naming it *C. helvola*, which by many botanists is considered to be a hybrid.—A report by the Rev. O. P. Cambridge, F.R.S., upon the spiders collected by Mr. Fisher, of the Jackson-Harmsworth Polar Expedition, was read by Mr. A. D. Michael. They consisted of three species, all belonging to the genus *Erigone*, one of which had been previously described, though not figured by Thorell; and another was new, but closely allied: the author proposes to call the latter *E. Fisheri*.

Geological Society, March 9.—W. Whitaker, F.R.S. President, in the chair.—Prof. J. W. Judd exhibited, on behalf of the Coral Reef Committee of the Royal Society, the lowest core (698 feet) from the boring at Funafuti (Ellice Island), and drew attention to the remarkable changes exhibited by the rocks obtained at this depth. The core from this boring (a mass of material more than a ton in weight) had been sent to this country by Prof. Edgeworth David, and was now being submitted to careful study. The last 20 or 30 feet of the boring was carried on in a rock which was of a very soft character, and highly but minutely crystalline. Microscopic examination shows that the rock is almost completely converted into a mass of very small rhombohedra, the organic structures being nearly obliterated; while a preliminary chemical examination seems to indicate that magnesia has been introduced into the rock to a considerable extent. The complete study, microscopical and chemical, of all the stages of the change which has taken place in this rock—a study which will be undertaken by Mr. C. G. Cullis—promises to throw much light on processes of rock-formation of very great interest to the geologist.—Note on Clipperton atoll, by Rear-Admiral Sir W. J. Wharton, K.C.B., F.R.S. This atoll, 600 miles from North America, in lat. 10° 17′ N., long. 109° 13′ W., possesses a lagoon which is now completely cut off from the sea. In this is a perfectly round hole where soundings of 20 fathoms or more are reported, on the authority of Mr. Arundel, and even deeper ones on that of the captain of a merchant-vessel. On the coral ring there rises a mass of modified trachyte, the subject of the following communication, about 60 feet in height. The great depth of the lagoon and the rock-mass on the ring are not compatible with the origin of the reef by subsidence or outward growth; and the possible hypothesis is put forth that this reef had grown on the lip of a volcanic crater, or on an island, such as Krakatao, in which the interior has been enlarged and deepened by volcanic explosion.—A phosphatised trachyte from Clipperton atoll, by J. J. H. Teall, F.R.S. Specimens from the projecting rock described in the preceding communication are dark brown, white, or cream-coloured. The brown specimens are trachytes, composed of glassy phenocrysts of sanidine set in a groundmass of microlitic felspars with brown interstitial matter. The light-coloured rocks are more or less altered trachytes, in some of which the glassy phenocrysts of sanidine may still be recognised. Analyses of several specimens show that the rocks all contain varying amounts of phosphoric acid.—The Pliocene deposits of the East of England, Part i. the Lenham Beds and the Coralline Crag, by F. W. Harmer. From the discussion of lists of fossils, a large number of sections, and a series of borings, the author endeavours to establish a number of propositions with regard to the Lenham Beds, the Coralline Crag, and the Red Crag. His evidence indicates that the Lenham Beds are older, perhaps considerably so, than the Coralline Crag.

Mathematical Society, March 10.—Prof. Elliott, F.R.S. President, in the chair.—Mr. A. N. Whitehead read a paper on the geodesic geometry of surfaces in non-Euclidean space.—Prof. W. Burnside followed with a paper on linear homogeneous continuous groups whose operations are permutable.—Mr. T. I. Dewar, in the absence of Prof. Greenhill, F.R.S., exhibited, with the aid of stereoscopes, some stereoscopic diagrams of pseudo-elliptic catenaries and geodesics.—Lieut.-Colonel Cunningham, R.E., contributed a supplementary note on Aurifeuillians.—The President briefly brought before the meeting a paper, by Mr. W. F. Sheppard, on the calculation of the sum of the *m*th powers of a large number of magnitudes, and then (Lieut.-Colonel Cunningham in the chair) read a paper by himself, on the transformation of linear partial differential operators by extended linear continuous groups.

Zoological Society, March 15.—Dr. Albert Günther, F.R.S., Vice-President, in the chair.—A communication from Sir Edmund Loder, Bart., contained copies of some photographs of the Beaver-pond at Leonardslea, Horsham, and gave a short account of the habits of the animals as there observed.—Mr. R. E. Holding exhibited a pair of horns of the Sunga or Galla Ox of Abyssinia, and made some remarks on the horns of this and other varieties of the humped cattle of India and Africa.—A communication from Dr. G. Stewardson Brady, F.R.S., on new or imperfectly-known species of Ostracoda, chiefly from New Zealand, was read. It contained descriptions of the Ostracoda collected in New Zealand by Mr. H. Suter, for the Zoological Museum of Copenhagen, and by Mr. G. M. Thomson, of Dunedin. It also included a description of an Ostracod from the Bay of Bengal, presenting some remarkable peculiarities of the mouth-organs, and constituting the type of a new genus, which was proposed to be called *Eupathistonia*. Of the New Zealand species treated of sixteen were described as new, and the new generic term *Trachyleberis* was proposed for the reception of *Cythere scabrocuneata*, Brady.—Mr. E. H. J. Schuster described a new species of flagellate Protozoan, which he proposed to name *Lophomonas sulcata*. This species occurred as an endo-parasite in the upper part of the colon of *Blatta americana*, Linn.—Mr. J. T. Cunningham read a paper on the early post-larval stages of the Common Crab (*Cancer pagurus*), and pointed out the affinity of that species with the Circular Crab (*Atelecyclus heterodon*).—Mr. Oldfield Thomas read a paper on some mammals collected by the late Mr. Henry Durnford in 1877–8 in Chubut, Patagonia.—Mr. Martin Jacoby contributed an addition to our knowledge of the phytophagous Coleoptera of Africa by describing forty-three new species of the groups *Halticinæ* and *Galerucinæ*, specimens of which had been collected by Mr. Guy A. K. Marshall in Mashonaland and West Africa. Two new genera, viz. *Cheiridisia* and *Pseudedusia*, were characterised.

Royal Meteorological Society, March 16.—Mr. F. C. Bayard, President, in the chair.—A lecture on photographing meteorological phenomena was delivered by Mr. A. W. Clayden, who gave details of his experiences as Secretary of a Committee of the British Association. After referring to the extreme value of photographic methods of recording the movements of instruments, the lecturer spoke of the real importance of preserving photographic records of all sorts of unusual meteorological phenomena, and emphasised the necessity of companion photographs showing the same scene under normal conditions. It was suggested that meteorologists throughout the country should co-operate with the Royal Meteorological Society in securing such records. The phenomena of the lightning discharge, as distinguished from those of a single flash, were next described and illustrated by a number of lantern slides. Some of the puzzles offered by lightning photographs were next alluded to, and the lecturer stated that he had repeatedly found that a single discharge lasted several seconds. Mr. Clayden then spoke of the "black" flashes shown in photographs, and described the steps by which, some years ago, he was led to the proof that they were merely a photographic phenomenon, but one which still remains unexplained. Passing on to a consideration of cloud photography, the various methods in use were explained and a large number of lantern slides were exhibited, in some of which the clouds were shown on a background of blue sky in nearly their natural colours, a result obtained by the employment of suitable developers on a specially prepared plate. The method employed at Exeter by the lecturer for the measurement of cloud altitudes was fully described. This differs from all other methods in using the sun as a reference point. Mr. Clayden then spoke of the difficulty in getting good pictures of cirrus clouds, and described the methods dependent on the polarisation of the blue light of the sky, but expressed a conviction that polarisation had nothing to do with their efficiency, which was really due to a general lessening of brightness which enabled the exposure to be properly judged.

CAMBRIDGE.

Philosophical Society, February 7.—Prof. Newton, Vice-President, in the chair.—"The coral reefs of Funafuti, Rotuma, and Fiji, together with some notes on the structure and formation of coral reefs in general," J. Stanley Gardiner. The author had accompanied Prof. Sollas' expedition to Funafuti in 1896. Funafuti cannot be regarded as a typical atoll, as it shows an elevation of at least 10 feet. Its islands are the remains of the original reef, and are rapidly being washed away; while the present reef is extending outwards by nullipore growth, forming masses outside and joining them on to the *rim* In Viti Levu, Fiji, soft limestone attains an elevation of 900 feet and alternates with "soapstone," which the author regards as a shallow water deposit analogous to the sand covering the inner reefs round Viti Levu. Many of the islands of Lau are of hard limestone, and represent raised atolls. In the case of Vatu Vara a vertical thickness of 1030 is attained. Evidence is given to show that the Fiji Group has been stationary for a long period, and that the conditions and formation of its reefs strongly oppose the subsidence theory. It is also contended that reefs spread outwards on their own talus, while lagoons are formed by solution. Evidence for the latter is given from the washing away of the limestone islands of Lau, the atoll-reefs of which are considered to have been formed by this means. The formation of coral reefs is due rather to nullipore than coral growth, and depends largely on the depth to which light can penetrate sea water.—"Methods for the demonstration of 'connecting threads' in the cell-wall," Walter Gardiner. The author gives further details of his "Kolossow-Safranin" method, and describes a modification of Meyer's method, which he calls the "iodine-acid violet" method. The paper also deals with the theory of both of the above modes of investigation.

February 21.—Mr. F. Darwin in the chair.—On some differential equations in the theory of symmetric algebra, Prof. Forsyth.—Discharge of electrification by ultra-violet light, E. Rutherford. In this paper the general phenomena of conduction under ultra-violet light were considered, especially from the point of view of the nature and velocity of the carrier of the negative electrification. By directing a blast of air against a plate on which ultra-violet light fell, it was shown that the whole or portion of the carriers could be removed with the current of air. The charged gas so obtained shows properties similar to the charged gas obtained in Röntgen conduction. A general method of determining the velocity of the carrier was given. By its means the velocity of the carrier for air was found to be about 1·4 cms per sec. for a potential gradient of one volt per cm. The velocity of the carrier is independent of the metal on which the light falls, but depends on the gas surrounding the plates. The velocity of the carrier was found to be inversely proportional to the pressure, a result which shows the carrier is of molecular dimensions. The results of the experiments are simply explained on the hypothesis that gaseous ions are produced at the surface of the negatively electrified plate. The theory previously advanced that the discharge was due to the disintegration of metallic particles under the action of ultra-violet light does not sufficiently explain the facts.—Röntgen photographs of metallic alloys, C. T. Heycock and F. H. Neville. The authors exhibited and described photographs taken by means of the Röntgen rays through plates of alloy. As the two metals forming the alloy possess different degrees of transparency to these rays, the photographs show the separation of the metals that has taken place during the solidification of the alloy. For example, alloys of gold and sodium containing less than 30 per cent. of gold are seen to consist of well-developed, very transparent crystals, which must be pure, or nearly pure, sodium, imbedded in a mother substance which solidified last, and which, from its comparative opacity, evidently contains the gold. On the other hand, alloys containing more gold show very opaque needles of gold imbedded in a less opaque mother substance. This mother substance was the same as that in the first-mentioned alloy; it solidified after the needles of gold had been formed. Photographs of alloys of aluminium and gold, and of aluminium and copper, were shown, which exhibited similar phenomena. The crystals of aluminium in the alloy with copper were perfect rectangular crosses several millimetres in diameter. The gold-aluminium alloys showed a precipitate of Roberts-Austen's compound of the formula $AuAl_2$; the crystals were well-marked tubes and octahedra.

MANCHESTER.

Literary and Philosophical Society, March 8.—Mr. J. Cosmo Melvill, President, in the chair.—The President announced that the title of the Wilde Lecture to be delivered by Prof. Michael Foster on March 29, would be "On the physical meaning of psychical events."—Mr. Thomas Thorp exhibited some celluloid films taken from Rowland's gratings of 14,438 lines to the inch.—"On the velocity of sound in a tube, as affected by the elasticity of the walls," by Prof. H. Lamb, F.R.S. The paper consisted in an application of the known theory of the vibrations of thin cylindrical shells to the calculation of the velocity of sound in a tube filled with liquid. This subject has already been treated by Korteweg, but the author's method is somewhat different, and one or two collateral results of interest are obtained. The paper included, further, an approximate investigation of the effect in a *thick* tube.

EDINBURGH.

Royal Society, January 31.—Prof. Chrystal in the chair.—An obituary notice of the late Edmund Chisholm Batten was read.—Dr. J. K. Talmage, a delegate to the Geological Congress of 1897, gave in a report of the meetings.—Papers by Dr. Thomas Muir, on the relations between the co-axial minors of a determinant of the fourth order, and by Prof. Nanson on the Ellipse-Glissette elimination problem, being purely technical, were laid on the table.—Mr. W. L. Calderwood read a paper on the migratory movements of Salmonidæ during the spawning season. After distinguishing between spring and summer runs of fish and calling attention to the dissimilarity between such runs and the autumn runs to the head waters for the express purpose of spawning, the author showed that these last runs could alone be considered as analogous to the runs in connection with the spawning habit of *Clupea allosa*, *C. finta*, or *Petromyzon marinus*. As to the conditions of water flow which seemed most favourable for Salmonidæ entering a tributary from a main river, Mr. Calderwood submitted several tables of data collected by daily observations in the spawning season of 1896-97. The results showed that most fish entered the particular tributary under consideration when the water was in quarter-flood; that temperature had apparently no influence upon the runs of fish; that a limited number of fish ascended during normal flow of the stream; that the sea trout commenced to ascend later than salmon, but remained a much shorter period, completing their spawning two months before the last salmon redd was observed. The author exhibited a diagram-chart of the spawning grounds, showing the distribution of salmon and sea trout redds, and the dates on which the redds were constructed.

PARIS.

Academy of Sciences, March 14.—M. Wolf in the chair.—Chemical actions of the silent discharge. Nitrogen compounds in presence of free nitrogen, by M. Berthelot. A continuation of similar work published in preceding numbers of the *Comptes rendus*. The substances dealt with included methylamine, dimethylamine, ethylamine, propylamine, isopropylamine, allylamine, aniline, methylaniline, benzylamine, toluidine, pyridine, piperidine, ethylenediamine, propylenediamine, phenylenediamine, benzidine, nicotine, acetamide, thiourea, acetonitrile, benzonitrile, aldoxime, phenylhydrazine, some nitro-derivatives, pyrol and indol.—On the estimation of carbon monoxide diluted with large quantities of air, by M. Armand Gautier. Remarks on the use of iodic anhydride for the estimation of minute quantities of carbonic oxide (1 in 20,000). The reaction is complete at 60°, the iodine being collected upon a roll of reduced copper and weighed. Better results are obtained by determining the carbon dioxide produced. Acetylene also reacts with iodic anhydride, and ethylene, although not reacting itself at 60°, possesses the peculiar property of completely preventing the oxidation of carbon monoxide.—On the importance of sugar considered as a food; new demonstration of the superior nutritive value of sugar compared with that of fat, taking the respective thermogenic values of the two foods into account, by M. A. Chauveau. Two series of experiments were carried out upon the same animal (a dog), one with a sugar and the other with a fatty diet; the results showed that sugar possesses great advantage over the dynamically equivalent proportion of fat. It is, then, erroneous to consider the nutritive value of a food as measured by its heat of combustion.—The development of the sponges, by M. Edmond Perrier. A controversial reply to a paper on the same subject by M. Yves Delage.—The expedition to Greenland of the Geographical Society of Berlin, by M. Marcel Bertrand. The present note deals only with that part of the work which concerns the structure of the ice and the movements of glaciers. The explanation given for the latter, which satisfactorily accounts for all the observed facts, is practically identical with that proposed by Thomsen, the arguments now added by M. de Drylgaski rendering these views more precise.—On the theory of numbers, by M. H. Laurent.—Integral invariants and optics, by M. Hadamard.—On the laws of reciprocity, by M. X. Stouff.—On the transformation of Abelian functions, by M. G. Humbert.—The energy of an electrified system, considered as distributed in the dielectric, by MM. H. Pellat and P. Sacerdote.—On the electric conductivity of thin plates of silver, by M. G. Vincent. The films were deposited on glass, and the thickness, which varied between 38μ and 170μ, measured by the methods of Wiener and Fizeau. The results of the measurements fell practically upon a straight line for thicknesses down to 50μ, below which an inflexion of the line took place. This critical thickness agrees well with the number obtained by Quincke in his capillarity experiments.—Some properties of electric discharges produced in a magnetic field. Assimilation to the Zeeman phenomenon, by M. André Broca. The hypothesis of the existence of ions in incandescent gases is sufficient to coordinate all known facts relating to the radiation of incandescent gases and also those relating to the electric discharge in gaseous media.—On the barometric formula, by M. Alfred Angot. The assumptions necessary for the accuracy of the Laplace formula are not strictly fulfilled in actual practice, so that the heights of an experimental balloon determined by the barometer and by triangulation respectively, may differ by as much as 300 metres in a height of 11,000 metres.—On the characters of the seasons of successive years, by M. P. Garrigou-Lagrange.—On the causes of the reciprocal replacement of two acids, by M. Albert Colson. An experimental study of the action of hydrogen sulphide upon the dry silver salts of orthophosphoric and pyrophosphoric acids.—On a new silicide of chromium, by M. Ch. Zettel. This silicide has the composition $SiCr_3$, and is obtained by strongly igniting in a Perrot gas furnace a mixture of copper, aluminium and chromic oxide. It is a well crystallised, very stable substance, which resists the action of all acids except hydrofluoric.—On a new method of fractionating the yttrium earths, by M. G. Urbain. The method consists of the fractional crystallisation of the ethyl sulphates. The results are similar to those obtained by the use of the acetylacetonates, the sulphates, and by the fusion of the nitrates.—On two modes of decomposition of some thiocyanic ethers, by M. Œschner de Coninck.—On some oxyethers of β-naphthol, by M. F. Bodroux. The ethyl, propyl, isopropyl, isobutyl, and isoamyl ethers are described.—On the product of oxidation of glycerine by the bacterium of sorbose, by M. Gabriel Bertrand. Dioxyacetone, $CH_2OH.CO.CH_2OH$, is the chief product; it was identified by means of its oxime.—On the sterilisation of liquids by filtration, by M. J. Hausser. Infusorial earth, calcined at 800° to 1000° C., powdered, and made into an emulsion with water deposits on any suitable filter support as a fine compact layer, which is capable of retaining the most minute suspended particles or micro-organisms. A thickness of ·4 to ·5 mm. is sufficient for sterilisation, and the velocity of filtration may be many times greater than with Chamberland filters.—The different modes of eliminating lime in rickets at different stages of the disease, by M. J. Babeau.—Embryogeny of the double larva of the Diplosomidæ, by M. Antoine Pizon. The results of Salensky concerning the development of the branchio intestinal apparatus are confirmed, and in addition the function of the epicardial tubes is established.—On the splitting of the cuticle, by M. P. Pautel.—The culture of *Tricholoma nudum*, by MM. J. Constantin and L. Matruchot.—Action of different salts upon the structure of plants, by M. Charles Dassonville. The structure of true plants varies greatly according to the chemical composition of the medium in which they grow, those solutions which are most favourable to the development of the plant being also those which produce in it the greatest differentiation.—On a new generic type of Schizomycetes, the *Chutinella*, by M. E. Roze.

DIARY OF SOCIETIES.

THURSDAY, MARCH 24.

ROYAL SOCIETY, at 4.30.—The Bakerian Lecture will be delivered by Dr. W. J. Russell, F.R.S. Subject: Further Experiments on the Action exerted by certain Metals and other Bodies on a Photographic Plate.
ROYAL INSTITUTION, at 3.—Recent Researches in Electricity and Magnetism: Prof. J. A. Fleming, F.R.S.
INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Cost of Generation and Distribution of Electrical Energy: R. Hammond.
INSTITUTION OF CIVIL ENGINEERS, at 4.—Prof. Boyd Dawkins will repeat the Sixth "James Forrest" Lecture on Geology in Relation to Engineering.
CAMERA CLUB, at 8.15.—Photographic Engraving in Intaglio: Colonel Waterhouse.

FRIDAY, MARCH 25.

PHYSICAL SOCIETY, at 5.—On the Circulation of the Residual Gaseous Matter in a Crookes' Tube: A. A. Campbell Swinton.—On some Improvements in the Roberts-Austen Recording Pyrometer, and Notes on Thermo-electric Pyrometers: A. Stansfield.
INSTITUTION OF CIVIL ENGINEERS, at 8.—Internal Governor Friction: H. O. Eurich.

MONDAY, MARCH 28.

SOCIETY OF ARTS, at 8.—The Thermo-Chemistry of the Bessemer Process: Prof. W. N. Hartley, F.R.S.
ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—Exploration on and around Mount Aconcagua: E. A. Fitzgerald.
INSTITUTE OF ACTUARIES, at 5.30.—Industrial Assurance: C. H. E. Rea.

TUESDAY, MARCH 29.

ROYAL INSTITUTION, at 3.—Simplest Living Things: Prof. E. Ray Lankester, F.R.S.
INSTITUTION OF CIVIL ENGINEERS, at 8.—Extraordinary Floods in Southern India: their Causes, and Destructive Effects on Railway Works: E. W. Stoney.
ANTHROPOLOGICAL INSTITUTE, at 8.30.—On the Natives of the Upper Welle District of the Belgian Congo: Captain Guy Burrows. (Illustrated with Lantern Slides and Objects of Ethnological Interest.)

WEDNESDAY, MARCH 30.

SOCIETY OF ARTS, at 8.—Telegraphy across Space: Prof. Silvanus P. Thompson, F.R.S.

THURSDAY, MARCH 31.

SOCIETY OF ARTS (Indian Section), at 4.30.—The Earthquake in Assam: Henry Luttman-Johnson.
ROYAL INSTITUTION, at 3.—Recent Researches in Magnetism and Diamagnetism: Prof. J. A. Fleming, F.R.S.
CHEMICAL SOCIETY, at 3.—Annual General Meeting.
CAMERA CLUB, at 8.15.—Prof. Joly's System of Colour Photography: Captain Abney, C.B., F.R.S.

FRIDAY, APRIL 1.

ROYAL INSTITUTION, at 9.—Liquid Air as an Analytic Agent: Prof. Dewar, F.R.S.

CÆNOGENESIS, THE EXPRESSION OF VARIOUS PHYLOGENETIC ENERGIES.

Kainogenesis als Ausdruck differenter phylogenetischer Energien. Von Dr. Ernst Mehnert, Privat-docent an der Universität Strassburg i. Elsass. Pp. 165, and plates. (Jena: Gustav Fischer, 1897.)

IT has become more and more evident, during the past twenty years, that the course of ontogeny may vary in a quite remarkable degree, even within the limits of a genus, and that the individuals of a species may present not unimportant differences in their respective ontogenies. This contradiction of the old-established belief that the type of development was similar for every considerable group of animals, has led to the abandonment of many of the older principles of embryology, and has introduced no small amount of confusion into embryological speculations. The question which confronts the investigator is this: which among the several modes of development which occur in closely allied species is to be regarded as primitive, and which secondary? In other words, what developmental features are palingenetic and what cænogenetic?

In the present work Dr. Mehnert seeks an answer to the question by a comparison of the developmental characters exhibited in homologous organs in individual embryos and in individual species with the characters exhibited by the same organs in adult individuals.

The definitive condition of an organ in an adult individual is, he says, the direct product of its phylogeny: it is therefore possible, by means of such a comparison, to recognise the characteristic correlative differences which obtain between the several ontogenies of homodynamous organs and their different degrees of phyletic perfection. He proposes to establish the principle that the law of close interdependence between phylogeny and ontogeny leads, as a consequence, to the appearance of cænogenesis; in other words, that cænogenesis is not, as is often assumed, an anomalous phenomenon, but is governed by strictly regulated principles.

In order to establish his thesis, Dr. Mehnert gives the results of his extensive researches on the fore and hind limbs of pentadactyle Vertebrates. He selected these as most appropriate to his purpose because the hand and foot are serially homologous, and because each is an organ composed of several dozen separate but approximate and partly homodynamous skeletal pieces, whose homologies can with some certainty be asserted in the whole group of pentadactyle Vertebrates. The different stages of prechondrified, chondrified, and ossified tissues also afford a series of changes whose estimation presents no difficulty.

Although he has worked over a great number of species, Dr. Mehnert confines himself to the detailed description of a few forms, selecting *Emys lutaria*, *Struthio*, some carinate birds, some Mammals, and some Amphibia.

The hand of Emys is, as is well known, typical. There are five digits, a distal row of five carpals, a proximal row of three carpals (radiale, intermedium and ulnare) and a centrale. In addition, Dr. Mehnert recognises certain "sesamoid" bones, an ulnare externum, a radiale externum, a centrale ulnare, and a centrale distale as belonging to a regressive skeletal series which was ancestrally equivalent to the other carpalia. He finds that the pendactyle arrangement is early sketched out in prechondrial tissue, and that chondrification begins in the forearm, and proceeds distally, each transverse row of carpalia, metacarpalia and phalanges chondrifying at the same time, the different rows successively in centrifugal order. This condition is compared to that of the foot of Struthio, which in the adult is two-toed, the third and fourth digits alone being developed. In young embryos, however, the foot is discovered to be pentadactyle; only three toes are visible externally, but in sections all five may be distinguished. The centres of chondrification appear successively, beginning in the proximal elements, and extending at short intervals of time to the distal elements. Of the metatarsalia, the third and fourth, corresponding to the permanent toes of the adult, are the first to be chondrified, the second and fifth are chondrified later; the first, being very rudimentary, disappears early. The conclusion is that in development permanent structures are accelerated, evanescent structures retarded. The same principle is illustrated by the development of the wing, and even more remarkably, for whereas it is usual in Vertebrata that the hind limb should lag behind the fore limb in development, in Struthio, and also in Apteryx, the adult reduction of the fore limb is foreshadowed in the embryo, since it lags behind the hind limb from the first. The same phenomenon is observed in Anura, in the adults of which the hind limbs are predominant as compared with the fore limbs. From a number of considerations, such as the limb of Baptanodon, and the embryonic condition of the limbs of Emys, Mehnert concludes that all the skeletal elements of the limb were primitively of equal size, and somewhat short and square in shape. If this were so, the long bones and the metacarpals, metatarsals and phalanges would be progressive elements, which have increased in length in the course of phylogeny, whilst the carpals or tarsals would be regressive elements, and on his principle the last-named should show evidence of retarded, the former of accelerated development. This he shows to be the case in Mammals and in carinate birds, in which the metacarpal precedes the carpal differentiation. By the comparison of a large number of forms Mehnert arrives at the general rule, that all the permanent digital rays are histologically differentiated at a very early period, and are the first to be divided into their components: in the regressive lateral digits the reverse is the case—they lag far behind the predominant digits, and they may eventually degenerate and disappear.

Mehnert claims to have shown that the ontogenetic retardation of the development of an organ is connected with a phyletic diminution of its functional importance. This he has undoubtedly done, and the special part of his work is full of interesting facts bearing upon minor anatomical problems. It is not, however, easy to follow him in his excursion into theoretical questions. Having asserted the nature of the parallelism between ontogeny and phylogeny, he proceeds to seek for a causal explanation, and finds it in the diminution and final loss of the faculty of cell-regeneration, due to the diminution and loss of the stimulus of functional excitation. In the case of limbs, the functional excitation is supplied by the stress to which the limbs are subjected in supporting the body weight. The primitive limb consisted of many rays; eventually five only were directly used for support, the remaining rows degenerated, and are now represented only by the "sesamoids." In further development of races, groups arose in which a lesser number of digits than five were used for support: the digits which were no longer used lost the stimulus of functional excitation and became degenerate, and their degeneracy was represented in ontogeny by a retardation in histological differentiation. Dr. Mehnert is clearly a Neo-Lamarckian as well as a follower of Roux, and he speaks, as clearly as Lamarck himself might speak, of the importance of individual effort in increasing or diminishing functional excitation. But there is one thing that Dr. Mehnert does not succeed in accounting for, nor has any Neo-Lamarckian yet succeeded in accounting for it, the constitution of the germ, which is such that the pentadactyle hand is first formed, even when it is destined to be monodactyle or didactyle in the adult, and this in an embryo developing under conditions which preclude the action of functional excitation. His principle of diminished cell-regeneration following upon diminished functional excitation obliges him to reject the teachings of those authors who assert a primary blastogenic phylogenesis, but he is constrained to admit some sort of preformation in the germ cell, and falls back on the specific energy of affinity possessed by every atom according to its position in the periodic system of elements. The course of speculation which starts from such premises can hardly lead to useful conclusions. The following is an example of the author's generalisations.

> "Ontogenetic evolutions are only the consequential manifestations of phyletic epigenesis, which again is in itself only a specialised evolution of the molecular energies and affinities which integrate the individual. That which in the earlier periods of the earth was epigenesis, or, as one may now say phyletic evolution, is now become ontogenetic evolution."

One can see what he wants to explain, but one cannot admit that he explains it. Towards the close of his work he states that—

> "individual growth and development is a mosaic-work of cells and organs produced by mass correlation which, as a result of different phyletic functional efforts, charges the germ with different regenerative energies."

The same idea might be expressed much more simply. The problem is, how and by what mechanism are variations in adult structures able to affect the germ in such a manner that they may be reproduced in the next generation? Mehnert seeks to prove that they do affect the germ, but he has not succeeded in suggesting the manner in which they can do so. Weismann's contention that acquired characters are not inherited has yet to be shown to be untenable, and his position will hardly be shaken by an argument which invokes the individual efforts of ancestors with limbs of theoretical construction in order to explain the observed facts in the ontogenies of their presumed descendants.

RADIATION VISIBLE AND INVISIBLE.

Light Visible and Invisible. By Prof. Silvanus P. Thompson, D.Sc., F.R.S., &c., Principal of, and Professor of Physics in, the City and Guilds Technical College, Finsbury. Pp. xii + 294. (London: Macmillan and Co., Ltd., 1897.)

THIS is an age of rapid growth of scientific knowledge when the theory of to-day becomes the established fact of to-morrow, and in no province have our ideas shown a more rapid advance than on the subject of radiations in the ether. First of all, the electromagnetic theory of Maxwell upheld that light was an electrical phenomenon, and this received its confirmation by the experimental genius of Hertz, and the subject of optics thus became attached to the domain of electricity. Later came the discovery, by Röntgen, of a kind of radiation entirely different from anything before known, and this was soon after followed by a discovery of a type of invisible radiation emitted by uranium and its salts, which apparently possess properties intermediate between ultra-violet light and Röntgen rays, but the cause of whose production is at present one of the mysteries of science. Besides these, many other types of radiation, either apparent or real, have been noted, and the subject of transformation of radiations at the surface of bodies is now engaging the attention of many observers. The last few years has thus been an era of unexampled activity in the study of radiations, and there is considerable evidence that this activity will be productive of still further results in the near future.

In this little volume—"Light Visible and Invisible"—Prof. Silvanus Thompson has published in full the six lectures delivered at the Royal Institution at Christmas 1897. At the outset we feel that the title of these lectures is rather a misnomer, for even a most imaginative person would hardly have expected that the volume was to include, under the title "Light Visible and Invisible," a lecture on the subject of electromagnetic waves, as well as a discussion of the properties and production of Röntgen rays.

These lectures are of necessity popular, and, as the author has very well said in his preface,

> "two things are expected of a lecturer who undertakes a course of Christmas lectures at the Royal Institution. In the first place, his discourses must be illustrated to the utmost extent by experiments. In the second, however simple the language in which scientific facts and principles are described, every discourse must sound, at least, some note of modernity, must reflect some wave of recent progress in science"

After reading the well-illustrated volume before us, no one will be disposed to deny the author has fulfilled the conditions laid down in the preface. The subject is very simply treated, and abounds with experimental illustrations; and though there is little, if anything, in the volume with which a scientific student would not be more or less acquainted, we cannot but admire the attractive way in which the information is laid before us. It came rather as a surprise to us, however, to find the "note of modernity" strongly sounded on the now well-worn subject of Röntgen rays.

The first lecture opens with a discussion of the elementary theory of light and shadows, and closes with some interesting details of Japanese magic mirrors, which are, I believe, not generally known. We then pass on in later lectures to the consideration of the visible spectrum and the eye, and here we are given an account of some of the effects of persistence of impressions on the retina, with its modern applications in the zoetrope and animatograph. In a series of six lectures it is manifestly impossible to treat of the whole subject of light with any degree of fullness, so that no apology is needed for the absence of any account of interference, diffraction, spectrum analysis, and many other branches of the subject, which are by no means the least important. The author has, however, a chapter devoted to the polarisation of light, which he considers a subject inherently simple rendered difficult by the nomenclature applied to it. In his own words—

> "Scientific men often fall into the habit of using long and difficult words to express very simple and easy ideas. The natural consequence is that people are often led to think that there is some difficulty about a really easy subject, whereas the main difficulty is to understand the meaning of the word selected to describe it. The word 'polarisation' used in optics is one of these terms. It sounds very learned and difficult, but the idea it is intended to convey is really very simple."

If this be true, the original inventor of the term must turn in his grave at the thought of the way he has unwittingly retarded the dissemination of scientific knowledge.

The elementary consideration of polarisation is admirably treated by the aid of simple mechanical analogies, and is made so ridiculously simple that no one could fail to grasp the fundamental ideas. The best and fullest part of the lectures, however, is that which deals with the ultra-violet portion of the spectrum, which is extremely well treated with a wealth of experimental illustration, and will be read with great interest by all students of physics. The discussion of the ultra-red portion of the spectrum leads up to the consideration of electromagnetic waves, of which a short account is given.

In the last chapter we reach the high-water mark of popular literature in an account of Röntgen rays, including, as it does, an interview of Prof. Röntgen by a newspaper reporter, and photographs of the hands of scientific celebrities, as well as of a cigar and spectacle case, with whose contents we are all now so familiar.

A short appendix is added to each of the lectures, treating with more completeness of one or more of the ideas which arose in the lecture. For example, we are given an account of anomalous dispersion brought up to date by the introduction of a brief account of Helmholtz's investigation of the change of refractive index with wave-length. A brief summary of the elastic solid and electromagnetic theories is appended, and also a *résumé* of recent work on invisible radiations.

The author, in his first lecture, used the conception of wave surfaces to explain the elementary theory of optics rather than the time-honoured geometrical method. Every one will agree with the author that the only true method of treatment is to disregard the source, and to consider only the march of the wave front; and the sooner it is incorporated in our elementary text-books on optics the better. In the appendix to the first lecture a method of determining the ordinary optical formulæ from the consideration of wave surfaces is shortly explained, and in the author's words, "these [formulæ] are, in fact, established much more readily on this basis than by the cumbrous methods that are consecrated by their adoption in every text-book of geometrical optics." This appendix is, however, rather out of place in a popular treatise of this kind, for it will be passed over by the ordinary reader, and it is not sufficiently complete to be of much service to the student of optics.

In the beginning of this article attention was drawn to the fact that the title of the volume hardly leads one to expect the nature of its contents. The author is apparently not quite sure whether he is justified in including an account of electromagnetic waves and Röntgen rays in a book on "Visible and Invisible Light"; at any rate, he considers it necessary to explain his nomenclature. On p. 272 (in a chapter entitled "Röntgen Light") we have the following:—

> "You will have noticed that I have spoken of these rays as 'Röntgen Light.' But are we really justified in calling it light? It is invisible to our eyes; but then so also is ordinary ultra-violet light, and so is infra-red light and Hertzian light. And there are other kinds of light, too, amongst them one discovered during last year by M. Becquerel and myself, which are invisible. But if the Röntgen light can be neither reflected nor refracted, neither diffracted nor polarised, what reason have we for calling it light at all? In fact, direct proof that it consists of transverse waves is wanting. Many conjectures have been formed respecting its nature. Röntgen himself suggested that it might consist of longitudinal vibrations. Others have suggested ether streams, ether vortices, or even streams of minute corpuscles. At one time the notion that it might be simply an extreme kind of ultra-violet light of excessively minute wave-length was favoured by physicists, who were disposed to explain the absence of refraction and the high penetrative power of the rays upon von Helmholtz's theory of anomalous dispersion, according to which the ultra-violet spectrum at the extreme end ought to double back on itself. The most probable suggestion yet made, and the only one that seems to account for the strange lateral emission of the rays right up to the plane of the antikathode, is that of Sir George Stokes."

We cannot at all agree with the author in speaking of Röntgen light, as it is a very misleading term, and presupposes a knowledge which we do not at present possess. The objection to the signification lies in the fact that the underlying view of what we call light is that which gives us a sense of vision. It is quite true that we call the ultra-red and ultra-violet portions of the spectrum invisible light, but that is purely a matter of convenience, as in the spectrum these waves are merely a continuation of the visible spectrum, and are not bounded by any hard and fast line; but it is quite another matter to apply the term to Röntgen rays, and when there is a perfectly general term "radiation" ready to our hand, it is far preferable to use it. It is far more accurate, as well as more scientific, to speak of Röntgen and uranium radiation rather than Röntgen and uranium light. It is time that the term light was restricted to its original signification, and it should not be carelessly extended to forms of radiation the nature and properties of which are probably very different to ordinary light vibrations.

E. R.

PHYSICO-CHEMICAL RESEARCH.

Arbeiten des physikalisch-chemischen Instituts der Universität Leipzig aus den Jahren 1887 *bis* 1896. Collected and edited by Prof. W. Ostwald, Director of the Institute. Four vols. Pp. x + 556; iv + 496; iv + 656; iv + 550. (Leipzig: Engelmann, 1897.)

THE year 1887 may be regarded as a red-letter year in the history of physical chemistry, for it was then that the birth of the theory of electrolytic dissociation took place.

Although the osmotic theory of solutions is somewhat older, it was also in 1887 that van 't Hoff published his classical memoir on the *rôle* of osmotic pressure in the analogy between solutions and gases.

These two theories, taken in conjunction with the law of mass action, form the starting-point of a new era in physical chemistry, and have thrown an entirely new light on miscellaneous facts taken from all domains of chemistry and physics.

The correlation of apparently isolated phenomena, which was then for the first time rendered possible, has materially advanced the study of philosophical chemistry.

Concurrently with the publication of these theories, Prof. Ostwald was transferred from Riga to the University of Leipzig, where he, assisted by numerous students of all nationalities, at once began the further investigation and application of the new and powerful weapons which had just been added to the armoury of the chemist.

An idea of what Prof. Ostwald has accomplished may be gathered from a perusal of the volumes now before us, representing only a selected portion of the work which has emanated from his laboratory during the past nine or ten years.

In all, the four volumes contain reprints of 104 papers published in the *Zeitschrift für physikalische Chemie*, which, by the way, was also founded in 1887. In many respects the papers are remarkable; not only are many of them classics, but they embrace nearly every department of chemistry. We are tolerably well acquainted with the specialisation which takes place in most of the continental laboratories, and we are often wearied with a harvest of papers all dealing with minute details and with different aspects of one and the same subject. This of course is necessary and important, but it is none the less tedious.

The volumes which are now brought under our notice form, on the other hand, a refreshing change; the majority of the papers are of fundamental importance, and are an eloquent tribute to the power and versatility of the leading spirit.

The occasion for their issue was the opening, at the beginning of the present year, of the new Physico-chemical Institute at Leipzig. In collecting the pamphlets for re-issue, the chronological order of publication has wisely been departed from, in order, by arranging the articles under their appropriate headings, to produce a more or less homogeneous budget, and thus to facilitate a general survey of the gradual development of each branch.

The contents of the first volume are classified into sections headed: general, the electrical conductivity of dissolved substances, and the electrolytic dissociation of acids and bases.

The advantages of this arrangement are obvious. By bringing together closely allied investigations, a great deal of time is saved and misconceptions are often prevented. The second paper in the volume, for instance, contains the diagrammatical description of Ostwald's famous experiment which is intended to remove the last doubts as to the validity of the assumption of free electrically charged ions. This experiment, it may be remembered, consists in bringing a negatively charged body up to an insulated vessel filled with a solution of potassium chloride, and connected by means of a siphon with a similar vessel at a little distance. If the siphon be now removed and then the charged body, there will be an excess of positively charged potassium ions in the adjacent vessel and negatively charged chlorine ions in the other. By conducting away the electricity the potassium, for example, assumes the ordinary form, and acting on the water present develops hydrogen, which can be collected in suitable apparatus and tested. This experiment has, in these columns and elsewhere, given rise to a great deal of unnecessary controversy which would probably never have been printed if the critics had been aware of the existence of the next important paper in the volume, namely, that on free ions, where the imaginary experiment was actually put to the test and found to give results in harmony both qualitatively and quantitatively with what had been predicted.

The second volume contains chapters on homogeneous and heterogeneous equilibrium, velocity of reactions and the determination of molecular weights; including a great many of the original papers by Beckmann and others on the theory and practice of the ebullioscopic and cryoscopic methods now universally employed.

Volume iii. deals entirely with electro-chemistry, and contains some of the most important recent contributions to our knowledge of this interesting branch. Contact electricity, the theory of the galvanic cell, with applications, and polarisation are treated of. Nowhere, perhaps, have the modern theories led to such brilliant results as in the department of electro-chemistry. It may be somewhat invidious to mention any investigation in particular; but, now that we are accustomed to look on the galvanic battery merely as an engine driven by osmotic pressure, we cannot allow this opportunity to pass without alluding to Nernst's classical memoir on the osmotic origin of the current.

The last volume of the series, besides several miscellaneous articles, contains an account of investigations on viscosity, diffusion, and optical and thermal phenomena.

The various pamphlets are reprinted word for word; and although the 'prentice hand is occasionally discernible, yet in many cases where corrections or additions have been rendered necessary these follow on immediately after the original article. Unfortunately some of the typographical errors present in the original have been reproduced, whilst others have here and there crept in. The equations at the top of p. 271, vol. iii., for example, are affected by both sources of error.

In conclusion, we have only to remark that if short notes giving a summary of contemporaneous work and ideas from other laboratories had been interspersed between the different sections and individual papers, the unity of the whole would have been such as to make the four volumes of the *Arbeiten* an excellent special treatise on physical chemistry.

Although this would undoubtedly have increased the value of the work to outsiders, it is perhaps rather antagonistic to its *raison d'être*, since it is primarily the collected published papers from the physico-chemical laboratory of the University of Leipzig. As such it is not only a welcome souvenir to those who have worked in the old laboratory, but it should be in the hands of all who are interested in physical chemistry. JOHN SHIELDS.

OUR BOOK SHELF.

Archives of the Roentgen Ray. Vol. ii. No. 2. *Radiography in Marine Zoology*, being a Supplement to the *Archives of the Roentgen Ray.* The British Echinodermata. By R. Norris Wolfenden, M.D. Cantab. (London: The Rebman Publishing Company, 1897.)

To deal with the above-named publications in inverse order, it may be remarked that Dr. Wolfenden's treatise of fifteen quarto plates and six pages of letterpress is the outcome of the radiography, by means of a 10-inch spark-coil, of a collection of Echinodermata dredged in the Orkney Seas during 1896-97. The author claims that it has been his endeavour "to show that the new method of radiography may be made of considerable service in zoology, as an accessory to dissection and description." The plates are mostly inartistic and of no practical value to the zoologist—at best but poor examples of the radiographer's art. While they betoken a laudable desire on their originator's part to develop the new light of physical science, they partake of the nature of mere experimental memoranda such as are usually made a basis for fuller investigation and allowed to pass unpublished.

Of the *Archives* it may be noted that with the number under review the title is changed from that "of Skiagraphy" to that "of the Roentgen Ray." The seventeen pages before us are chiefly conspicuous as containing a full report of the inaugural meeting of the Röntgen Society of London, a combination of a conversazione, a trade exhibit, and a concert, set around a presidential address. The latter, reported *in extenso*, deals with the history, development, and application of the Röntgen discovery, to the invoking of Shakespeare. Special stress is laid upon the advantages likely to accrue to the medical profession by the employment of the X-ray tube; and since the members of that profession seem likely to profit both by its use and its user, they ought for the future to be among its foremost advocates. It is thus but appropriate that the body of the *Archives* should be devoted to a brief description of five plates mainly illustrative of the osteological phenomena of "acromegaly"—which we would remark is now more correctly known as megalacria. Beyond this there are a few desultory notes of a practical order, but we are unable to detect anything which might not have been communicated in the customary form to one or other of the established scientific societies. We fail to see the justification for the foundation of a new society, and shudder at the assertion that there are already "three journals established for the publication of observations and discoveries connected with the Roentgen rays," not to say at the suggestion of rivalry in the wording of the cover of the issue under review. Concerning the zoological departure, however, a good purpose will have been served, in the awakening of the mind of the physicist to the fact that animals exist and have a form and symmetry capable of scientific treatment.

Practical Electricity and Magnetism. By John Henderson, B.Sc. (Edin.), A.I.E.E. Pp. xv + 388. (London: Longmans, Green, and Co., 1898.)

THIS little volume, the second of a series of laboratory manuals at present being brought out by Mr. Henderson in conjunction with Mr. Joyce, has certainly many points about it which are not only original, but which should also render it of the greatest value in the physical laboratory.

It is designed "to provide a course of instruction for carrying out a progressive series of experiments in electricity and magnetism," and, though it is written, not for technical students, but for students of science, one is nevertheless struck with the author's extremely high ideal of laboratory experimental work. The student receives at the outset a preliminary admonition which cannot be described as other than most excellent and to the point. He is assumed to have plenty of time at his disposal, and not to be engaged in getting through a certain set of experiments in a given time: conditions which can hardly be expected of students preparing themselves for any practical examination, or even in every case of students engaged in original research. The writer's effort to inculcate an almost impossible ideal is none the less a most praiseworthy feature of the book.

The descriptions of recent experimental work are well up to date, though perhaps such work has received here and there an almost undue prominence. At the end of each section, a list of references to original papers bearing on the subject is given. These lists, which are carefully prepared, will recommend the book to all who are engaged in looking up in detail any particular branch of the subject.

The notation used is not always happily chosen, as, for example, the double meaning of the letter *R* on p. 108-9; and the book is by no means entirely devoid of unfortunate mistakes, as in the table on p. 378, where the mechanical equivalent of heat is given as "42400 grms. per °C" instead of "42400 grm.-cms. per °C." Such faults will, however, no doubt disappear in a second edition.

Much practical and detailed advice on the carrying out of experiments is given, which it would be hard to find in so concise a form elsewhere; and, though the manual is for this very reason not exactly readable, yet this portion of the work, together with the tables of references to original papers already alluded to, and the concluding set of numerical tables and physical constants, combine to make up a most useful work for the physical laboratory.

D. K. M.

La photographie et l'étude des nuages. Par Jacques Boyer. 8vo. Pp. vi + 80. Twenty-one illustrations. (Paris: C. Mendel, 1898.)

AT the International Meteorological Conference at Munich, in 1891, a Committee was formed to consider the question of concerted observations on the direction of motion and the height of clouds, and subsequently various countries were invited to undertake special observations during a year commencing May 1, 1896, a period which was afterwards extended until August 1897. A Committee was also appointed to prepare a Cloud Atlas, based on the classification of Dr. Hildebrandsson and the late Mr. R. Abercromby, and instructions for observing and measuring the altitudes of the clouds by theodolites and photogrammeters were prepared by experts in this branch of meteorological science. The present handy little volume is the outcome of this action, and brings into a small compass a considerable amount of useful information which is spread over various publications, some of which are not easily accessible. It is divided into four parts: (1) the history of the subject from the middle of the eighteenth century; (2) classification according to the atlas above referred to, with a number of illustrations; (3) description of the photographic apparatus employed, and (4) the method of measuring the pictures obtained. The two last chapters will be very valuable for any one proposing to undertake the difficult task of photographing the clouds, and of determining their heights and movements. In referring to the various attempts at cloud classification, we do not find any mention of "Cloudland," by the late Rev. W. C. Ley.

Proceedings of the London Mathematical Society. Vol. xxviii. Demy 8vo, pp. 594. (London: Francis Hodgson, 1897.)

This collection of thirty-four original papers on every branch of mathematics affords abundant evidence that English mathematicians are not behindhand in moving with the times. If proof be needed that the younger generation of mathematicians are quite following in the lines of those that have gone before them, it may be sufficient to mention that at least six of the papers are by men who have graduated at Cambridge since the year 1886. As might be expected, "Partitions" and "Groups" occupy a prominent place, seven of the papers being devoted to them. The former of these two subjects is ably introduced by Major MacMahon, F.R.S., in his address on "Combinatory Analysis," delivered on retiring from the office of president; and the publication of the outlines of seven lectures on the "Partitions of Numbers," delivered by the late Prof. Sylvester at King's College, London, in 1859, is another important feature. On the other hand, "hyper-Euclidian geometry" is conspicuous by its absence, and applied mathematics is represented by eight papers only.

During the past year the London Mathematical Society has lost two members in addition to the late Prof. Sylvester: the Rev. Alexander Freeman, who died on June 12, 1897, and Lieut.-Colonel John Robert Campbell, who died on June 23. Colonel Campbell, besides serving on the Council, was a benefactor to the Society, and we understand that had it not been for his munificence it would have been impossible for the Society to issue such large and interesting volumes of *Proceedings* as the one now before us.

First Year of Scientific Knowledge. By Paul Bert. Translated by Madame Paul Bert. Revised and partly re-written by Richard Wormell, D.Sc., M.A.; and Montagu Lubbock, M.D. Pp. vi + 417. (London: Relfe Brothers, Ltd. Paris: Armand Colin and Co.)

This is a revised edition of a work which has had a very successful career, but is constructed upon a plan which has little to commend it. The revision has consisted in bringing the information into line with current scientific knowledge, the plan of the book remaining as in the original. The rudiments of zoology, botany, geology, physics, chemistry, animal physiology, and vegetable physiology are all described in the four hundred pages which constitute the text, so that the book is comprehensive in its scope, if nothing else. The chief fault we have to find is that far too many technical terms are defined and used, so that the unfortunate pupils who are introduced to natural history by this book will be given the idea that science consists chiefly of words of Greek origin, and an unpronounceable terminology.

Who's Who, 1898. Edited by Douglas Sladen. Pp. xviii + 846. (London: A. and C. Black, 1898.)

This is undoubtedly the handiest biographical dictionary and compendium of information, referring to prominent persons and their doings, in existence. It contains nearly seven thousand biographies—mostly autobiographies—of the leading men and women of the day, and a large amount of information in addition. Among the general contents of interest to men of science is a list of Royal, National and learned societies, showing the addresses of the societies, secretaries' names, annual subscriptions and other conditions of membership. We notice also a table of university degrees, with the correct explanation of each, a list of chairs and professors in the great universities of the United Kingdom, arranged alphabetically by their chairs, and a list of Fellows of the Royal Society (most of whom appear among the biographies). The volume is one to be kept on the writing table for ready reference; and it possesses the merit of including in its pages biographical details of more men of science than usually figure in similar reference books, though even now some of the minor literary lights could be struck out with advantage to make room for well-known scientific men who have been omitted.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

Mechanism of Self-fertilisation in the Banana.

I propose to describe here the mechanism of fertilisation in the banana plant.

(1) *Packing of the inflorescence.*—The inflorescence in this plant is packed air-tight in the large red-coloured bracts, whose margins are secured in place by a sort of cement. If we remove one of these bracts and examine the buds within, we find that the reproductive organs are also packed air-tight in the perianth. A closer examination of this packing is necessary to understand its efficiency.

The perianth consists of an outer whorl and an inner whorl; the outer one consists of three sepals, usually united into an elongated concave hood. (Sometimes, instead of the three being united together, only two are united and one is free, which in the bud is partially overlapped by the other. Very rarely the three are quite free. In about fifty examples I examined, I got only one flower with all the three sepals distinct.) The margins of the hood are folded inwards, so that they overlap each other. There is no fixed rule as to which is the outer, and which the inner, sepal. Sometimes the right overlaps the left, or *vice versâ.* This overlapping is not complete throughout their length, and cannot possibly be so. For, to ensure the packing being air-tight, the pectinate inflorescence must necessarily be concavo-convex, *i.e.* convex without and concave within; and obviously any cylindrical tube bent concavo-convexly must necessarily leave a gap or a window at the bottom (see Figs. 1 and 2).

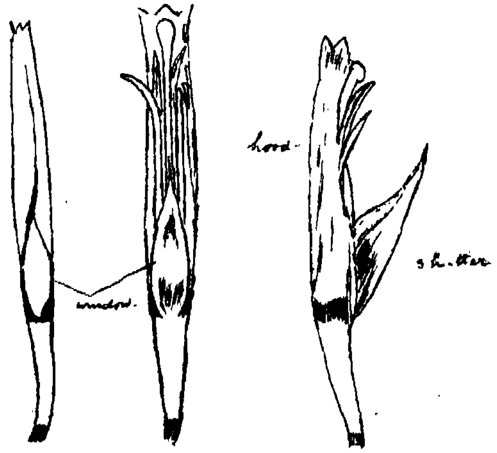

Fig. 1 Fig. 2 Fig. 3

This window would be a very weak point in the packing, and hence most accessible to insects or other injurious agencies if the outer packing became loose by accident. This weak point must, therefore, be guarded first; and we see that nature has done it by closing the window with one of the petals of the inner whorl. This petal is convex in front and concave behind, while the hood is convex behind and concave in front. This arrangement shuts off the window completely (Fig. 3). The petaloid shutter is secured in its place, on either side, by the margins of the hood to nearly an eighth of an inch. These margins are very much thinned out, and are also cemented together. The shutter, being on the concave side of the bud, comes in contact with the convex bract beneath, which thus helps to keep it in position. The top of the hood is closed similarly air-tight by its margins. The inner whorl—*i.e.* the corolla—is represented usually by the shutter alone. Sometimes, however, two petals are present, and very rarely all the three.

The male organs, thus tightly packed, can neither move from their place, nor can they be assailed by any foreign element from without.

(2) *Arrangement of the stamens.*—On removing the hood and the shutter we come to the andrœcium, which consists of four or five stamens. The filaments are petaloid and erect, thus embracing the pistil completely. The anthers are adnate or dorsifixed. They are also introrse, *i.e.* turned towards the stigma.

Let us now proceed to the pistil, and examine it in the different stages of its growth. In the early state—*i.e.* before it is ripe, and before the anthers are ripe also—the style and the stigma project beyond the andrœcium. If this state continued, self-fertilisation would be impossible. The stamens must either overtake the stigma, or the stigma must be at the mercy of insects or the wind for pollination. The stamens are not quick enough in growth to overtake the stigma; so what happens is this. By the time the anthers are ripe, the style shortens in length by bending nearly at right angles in two places (often marked by horizontal grooves in early stages), and thus brings the stigma in contact with the pollen (see Figs. 4 and 5). After pollination is completed, the style straightens again and projects, as before, beyond the andrœcium (see Fig. 6). Stages intermediate between Figs. 4 and 5, may be seen if we examine the flowers from without inwards. With the straightening of the style, the anthers become free and curve outwards. The bracts fall off; the shutter drops away; the hood withers, and the style dries gradually.

Stereoscopic Projection of Lantern Slides.

IN your report of the meeting of the Physical Society on February 26 (NATURE, p. 454), I notice an account of the exhibition, by Prof. T. C. Porter, of a somewhat complicated apparatus for exhibiting lantern slides in stereoscopic relief. An equally elaborate arrangement, depending on the use of polarised light, was exhibited at the British Association at Nottingham in 1893. It may possibly, therefore, be of interest to call attention to the much simpler means of accomplishing the same result, which suggested itself to me some time ago, but I subsequently found that it had been invented previously by Lieut.-Colonel Moëssard under the name of *monocular* stereoscope (*Cosmos*, May 23, 1896).

In this stereoscope one eye views one of the pictures directly, while the other eye sees the other picture after reflection at two mirrors, the angle between whose planes can be adjusted so as to bring the image into apparent coincidence with the picture seen by the first eye. In viewing distant pictures, such as lantern slides, a projecting partition, with a flange whose breadth is nearly equal to the distance between the two eyes, is all that is necessary to prevent either eye from seeing the wrong picture.

For lantern work, either two pictures could be projected side by side with separate lanterns, or two small views could be photographed side by side on the same slide, and thus enable stereoscopic effects to be shown with a single ordinary lantern.

Moreover, by turning the arrangement of mirrors through 90° it can be made to displace the image seen by one eye *vertically* instead of horizontally. This would enable the two pictures of an oblong view to be projected *one above the other*, instead of side by side, and viewed with the same apparatus as before, but differently arranged. As regards the foreshortening of the upper picture, this would be to a great extent compensated for by the fact that the lantern itself projected the picture upwards.

It is evident that two pairs of mirrors, one for each eye, could be used if desirable. G. H. BRYAN.

The Aurora of March 15.

I WAS fortunate enough to witness the display of the aurora on the night of the 15th, and think that some of the appearances may be of interest to those who did not see them, but who have recorded the accompanying magnetic disturbances.

The display began in the north-east about eight o'clock, by the appearance of a brilliant band of light, rising from behind a cloud 45° from the horizon, and extending about 30° in a south-westerly direction. This band might have been mistaken for a search-light, the edges were so sharp. The colour was the characteristic greenish hue of the aurora.

After persisting steadily for five minutes the band gradually broadened and shortened, and became a bright patch, which continued until the end. The display spread over the northern sky to the west, where another patch appeared. At nine o'clock the display was very fine, with two patches east and west, and right overhead seemed to be the apex of a parabola with beams of light streaming northwards. Looking southwards, occasional flashes of a yellowish pink colour could be seen. About ten o'clock the whole energy of the display seemed to become concentrated in the east and west patches, and great flashes of light connecting the two. After this the brightness seemed to gradually diminish.

So bright was the aurora at its height that the grey granite walls of the houses were illumined by the flashes.

Aberdeen, March 25. A. GEO. SMITH.

On Phosphorescent Sap in Superior Plants.

IN answer to the question of Prof. Giglioli in NATURE of March 3 (p. 412), I beg to observe that in Meyen's "System der Pflanzen-Physiologie," which was certainly in its time a standard work, there is to be found in vol. ii. p. 203 (Berlin, 1838) a short but concise statement of the phosphorescence of the milk-juice in *Euphorbia phosphorea*, on the authority of v. Martius ("Reise in Brasilien," ii. pp. 726 and 746), as also a reference to a communication by Mornay (*Philosophical Transactions*, vol, vi. p. 279), on the phosphorescence of the milk-juice "in einem rankenden Gewächse, Cipo de Cunanam genannt, welches zwischen Monte Santo und dem Flusse Bendego wuchs und wahrscheinlich eine Asclepiadee oder ein Apocynee ist." M. W. BEIJERINCK.

Delft, Holland.

A Remarkable Case of Correlation.

A VERY interesting case of correlation is recorded in the *Bulletin* of the Botanical Department, Jamaica, for December 1897.

Particular attention has been paid lately to the selection of good Ripley pine-apples, and it is found that if there is a broad red stripe in the centre of the leaf the fruit will turn out good; in other cases the fruit goes into holes at the bottom, and is attacked by ants. S. N. C.

MRS. BISHOP'S KOREA.[1]

WHEN, after returning from the perils and hardships of her adventures in the Bakhtiari country of Persia, Mrs. Bishop announced her intention of making an extensive journey in Eastern Asia, her friends knew that she would not return without having something of interest to tell regarding her travels in little-known regions. Although unfortunately ignorant of the languages of the countries in which she was to travel, and therefore dependent on others to a large extent, Mrs. Bishop had most carefully prepared herself for making all necessary observations and records. She is particularly to be congratulated on her skill as a photographer. The points of view were very carefully chosen, and the exposures accurately calculated, while the practice of developing the plates at the time, allowed duplicates to be taken if the first negative proved defective. The result is one of the best collections of photographs which we have seen as the result of a travelling amateur. We must congratulate the publishers also on the manner of reproduction employed: the more important views are printed as separate plates by the half-tone process, the others are reproduced as line-and-stipple blocks in the text, allowing the book to be printed on unglazed paper, and giving the volumes a lightness which is as desirable as it is rare.

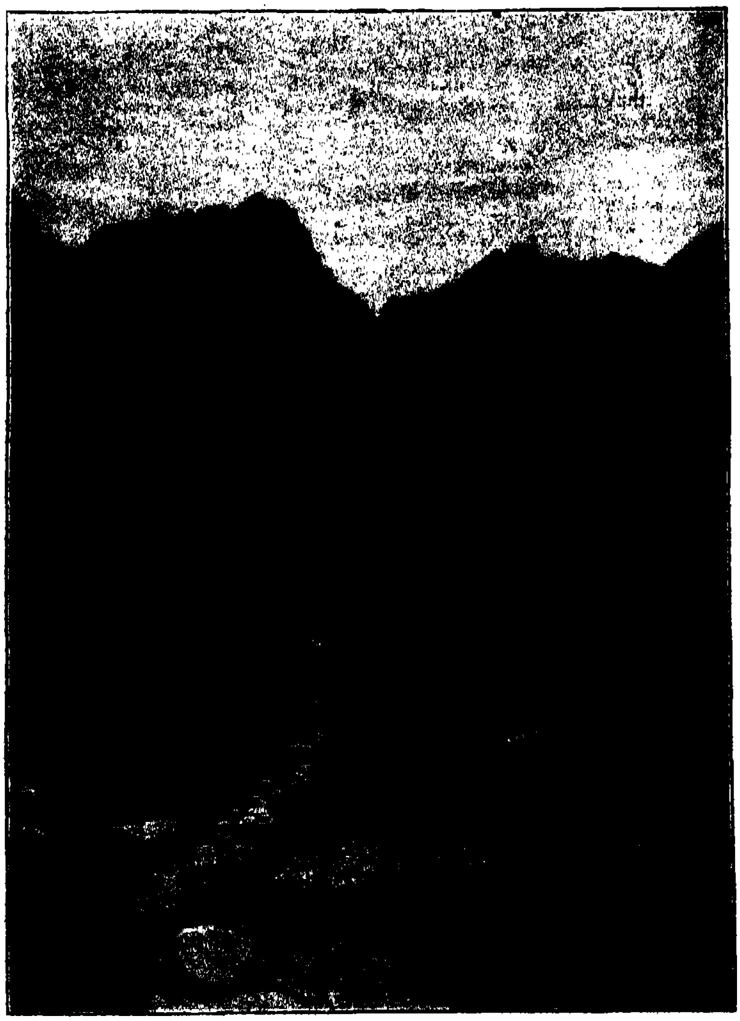

FIG. 1.—A Canyon in the Diamond Mountains.

Mrs. Bishop deals here with only a portion of her recent travels. Her important tour through Sze-chuan, on which she read a paper to the Royal Geographical Society—the first paper ever read by a lady to that Society—is not referred to, and the journey through Manchuria is but lightly touched on. Korea is the central theme; and although the interests of the authoress were obviously with the social and political aspects of the country rather than with its physical and biological conditions, she succeeds in giving an excellent general account, all the more valuable because not a little rubbish has been written by chance visitors at the treaty-ports. We may be pardoned if we feel a little regretful that—for example—the character of the interesting rock in the foreground of the photograph we reproduce (Fig. 1) is not described; but doubtless, the pioneer work having been accomplished, scientific travellers will follow, who can tell us whether the stone is merely water-worn or bears the sign-manual of ice.

We have one definite fault to find, and that is with the spelling of Russian place-names. Wladivostok is an incorrect transliteration. A German would write Wladiwostok properly enough; but the Russian letter *B* can only be represented by *v* in English, and the usual form of the name *Vladivostok* is the only correct one. There are some other slips—such as Richofen for Richthofen, and the terms flora and denudation are applied in a popular rather than a scientific sense.

Mrs. Bishop describes her landing at Chemulpo, and the journey to Seoul by land; one could hardly say by road, for "traffic has worn for itself a track, often indefinite, but usually straggling over and sterilising a width enough for three or four highways, and often making a new departure to avoid deep mud-holes." A residence in the insanitary and unsavoury Seoul followed, and then a journey by sampan up the south branch of the Han River, which was previously almost unknown to Europeans; then up the north branch of the river, and on ponies to the Diamond Mountains, and northward to Wönsun on the east coast. Returning to Chemulpo by sea, Mrs. Bishop was strongly advised by the British Consul to leave the country, and so crossed to China and made her way *viâ* Newchwang into Manchuria. It was a journey full of interest and of danger from floods, and the undisciplined Chinese armies on their way to the Korean war. Then she went *viâ* Nagasaki to Vladivostok, studied the Korean colonies in Siberia, and tried to enter Korea from the north; but the rivers were impassable, and another long sea-voyage was necessary. A second residence in Seoul led to a journey northward along the old road to China for 200 miles. A third and final visit to Seoul occupied the last few months of 1896. As Mrs. Bishop lived in the village inns when travelling, and was in constant communication with the diplomatic agents and missionaries while in the capital, her opportunities for seeing native life and learning the state of affairs in the country were exceptionally good.

Her special study was the people. In a note we learn that the average size of 1060 men, measured at Seoul in January 1897, by Mr. A. B. Stripling, was height 5 ft. 11⅛ in., chest-measurement 31 in., and circumference of head 21⅝ in. The maximum figures were respectively 5 ft. 11⅞ in., 39¼ in., and 23¼ in. The physique is generally good, and the people possess many amiable qualities. The total population is estimated at from 12,000,000 to 13,000,000. Most of the people are very poor, and have no inducements to thrift; any wealth they may gather is at the mercy of the official class, who are mainly, if not entirely, responsible for the miserable condition of the country. Under the just rule of the Russians in Eastern Siberia, Mrs. Bishop found the Korean emigrants happy and enterprising, making good profits from their farms and inhabiting comfortable houses. Given good government, people and resources being as they are would ensure prosperity to Korea. Into the tangled political history of the unhappy country we cannot enter here, nor can we refer to the many curious customs, ceremonials and beliefs, which are set forth at considerable length. These, perhaps, constitute the most valuable part of the book, for Mrs. Bishop caught Korea in an interesting transition period, when the old subjugation to China was being repudiated for ever, and reforms of many kinds were being introduced. The Altar of the Spirits of the Land, at which the ceremony of repudiation was carried out, is shown in Fig. 2. Few contrasts are more striking than that presented by Seoul at her first and at her last visit; when the filthy chaos of huts surrounding the palace gave place to well-ordered streets of good houses. The problem of the fourfold influence of Russian, Chinese, Japanese and European interests is very well handled. Of the industries of Korea the most interesting is the cultivation of gin-seng, the description of the processes employed in the manufacture of the dried root being, we believe, the fullest yet published.

[1] "Korea and her Neighbours. A narrative of travel, with an account of the recent vicissitudes and present position of the country." By Mrs. Bishop (Isabella L. Bird), F.R.G.S. With a preface by Sir Walter C. Hillier, K.C.M.G., late H.B.M.'s Consul-General for Korea. With maps and illustrations. 2 vols. (London: John Murray, 1898.)

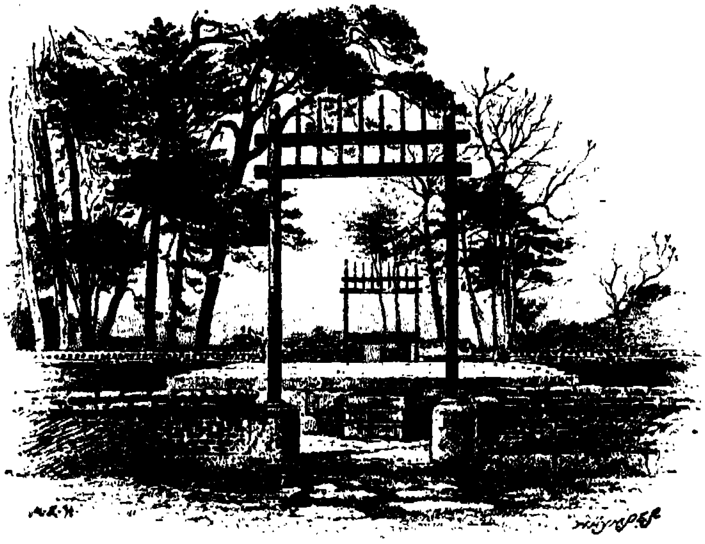

FIG. 2.—Altar of the Spirits of the Land.

The future of Korea is still uncertain, but it is bound to play a prominent part in the politics of the Far East; and this book will hold a place as a valuable work of reference for many years to come.

HUGH ROBERT MILL.

ASTRONOMICAL RESULTS FROM THE CAPE OBSERVATORY.[1]

THESE three volumes, issued under the superintendence of Dr. Gill, form in some respects a very remarkable production. Not so much on account of the very numerous observations, whose discussion furnishes forth these weighty books, as by reason of the widespread assistance rendered by many astronomers, whose energies Dr. Gill has quickened, whose results he has collected, stamped with his own individuality, and incorporated in the "Annals of the Cape Observatory." There are very few instances in which the director of an observatory has been willing to take up a laborious piece of work at the suggestion of an astronomer, however eminent, go through the wearisome task of making the observations, and then be willing to hand over his results to an independent authority for final discussion or criticism. It is this quality of self-abnegation, which strikes us as so complete and worthy of imitation. We congratulate Dr. Gill on his tactful skill, by which he has emerged from his self-imposed task, without friction with his collaborators, and been able to present to the world, in a complete form, the result of a scheme which he carefully planned and carried to a successful issue. We think it an especial merit in Dr. Gill's work, that he has perceived the value of strengthening his heliometer observations by combining with them the results made with similar instruments elsewhere. It was quite within his power and instrumental means to have derived the solar parallax from observations of the asteroids made solely at the Cape Observatory. Other observers could have done the same work, but separate discussions, made at irregular intervals and under varying conditions, do not possess the proportionate authority that attaches to one discussion made with several instruments on a combined plan. Moreover, one feels that the last word has been said, for some years at least, on this subject of solar parallax, by means of heliometer observations. Every observer must feel that, singly, he cannot do more than has already been done collectively. There can be no temptation to repeat the work. Consequently the owners of this class of instruments are freed from this particular investigation, for which the heliometer seems especially well fitted, and are at liberty to pursue other inquiries with advantage. It might be worth while just to mention, that to get the full power of a heliometer a considerable number of meridian observations is necessary. In this case some thousands came under the discriminating examination of Prof. Auwers. To use this mass of observations on one series of measures would be extravagant, but when combined with all the heliometer observations in a final inquiry, this cost of time and labour is disregarded, since they contribute to the increased accuracy of so large a body of measures. It is a true economy which Dr. Gill has practised, and the success which has followed it will bear much fruit in the future.

In the inquiry from which the solar parallax is deduced, we notice that no less than six observatories have contributed heliometer measures. Besides that of the Cape, we have New Haven (Yale College), Leipzig, Göttingen, Bamberg, and the Oxford Radcliffe Observatory, all furnishing measures of some or all of the three planets, Iris, Victoria, and Sappho, from stars in a previously selected zone, through which the planets passed. Several have further assisted by making a careful triangulation of the selected stars. The position of these stars has been determined at "all the principal observatories," to use Dr. Gill's phrase, who apparently grew tired of enumerating all the institutions to which he is indebted for the completeness of this section of the work. The final value of the coordinates has been made the subject of a discussion by Prof. Auwers, which may well form a model for similar inquiries, and will be carefully studied by the professional astronomer engaged in similar work. Into minute details which arise in this section, as well as in the use and reduction of the heliometer measures themselves, it is impossible to enter here with sufficient fullness to make the involved process at all clear. The whole interest centres in the nicety with which small residuals are treated. For a similar reason it would be impertinent to offer any criticism which would imply that we have given to the volume the same anxious study and consideration which the combined authors have devoted to their subject. Dr. Gill has supported himself by the ablest authorities in meridional astronomy, his own experience with the heliometer to which he has devoted years of study in perfecting the mechanical arrangements and details is profound, and we have no doubt that we have here all that can be effected by sagacity and experience in deriving the best results from observations which are as perfect as we yet know how to make them. The final outcome of the observations which, in their main intention, were devoted to deriving the value of the solar parallax may be thus presented.

---

[1] "Annals of the Cape Observatory." Vol. iii. The Cape Photographic Durchmusterung. Vol. vi. Solar Parallax from Heliometer Observations of Minor Planets. Vol. vii. Solar Parallax from Observations of Victoria and Sappho. (London: Published by order of the Lords Commissioners of the Admiralty, 1896.)

Heliometer observations of	Iris, discussed by	Dr. Elkin..	8″·8120 ± 0″·0090
	Victoria ,,	Dr. Gill ..	8·8013 ± 0·0061
	Sappho ,,	Dr. Gill ..	8·7981 ± 0·0114
Meridian observations of	Iris ,,	Dr. Auwers	8·771 ± 0·130
	Victoria ,,	Dr. Auwers	8·845 ± 0·051
	Sappho ,,	Dr. Auwers	8·626 ± 0·118

The mean value from the heliometer measures is 8″·8036 ± 0″·0046, while the meridian observations give 8″·806 ± 0″·030, but for reasons stated, Dr. Gill is inclined to adopt as a final value 8″·802 ± 0″·005. Though this result of itself would be a satisfactory outcome, the accuracy of the observations permits some other astronomical constants to be derived, either directly or through their relations with other known constants. The Victoria observations give with some confidence the mass of the moon $= \frac{1}{81·702 \pm 0·094}$. For other constants, such as the nutation, it is necessary to assume the luni solar precession. The value adopted is 50″·367 ± 0″·004, but the source from which it is obtained is not very clearly stated, neither is the epoch to which it refers. Apparently it is taken from Newcomb's discussion in the *Astronomical Journal*, No. 359; but in that paper we have not been able to find this particular value, nor the probable error with which it is accompanied. With this value of the precession, however, and the exact amount is immaterial for this purpose, the constant of nutation is 9″·2068, and pursuing the same line of inquiry the constant, $\frac{C-A}{C}$ (employing the ordinary notation), is 0·00328251. Adopting Clark's value for the equatorial radius of the earth, the aberration constant is found to be 20″·467 ± 0″·012. Here as elsewhere the most probable value of the solar parallax is assumed 8″·802.

The remaining volume, which contains the southern "Durchmusterung," between the limits − 18° to − 37° declination, is in its way quite as remarkable as the two volumes which we have been considering. Herein we have the first-fruits of the application of photography to the determination of star positions on a large scale. The old and the new methods are brought sharply into contrast. One would naturally like to institute a comparison between the time necessary for the production of these zones, and that required for similar work, either at Bonn or Cordova. But such a comparison is not easy, nor probably would it be fair. The plates that were taken at the Cape were measured at Groningen. Much time must have been lost in correspondence and in settling the details of a new method. Experience had to be acquired in the most suitable methods of measuring with new and untried apparatus. Prof. Kapteyn was necessarily occupied by his University duties, and could only devote his leisure to the preparation of the catalogue—a leisure which he gave unstintingly; and Dr. Gill is to be congratulated on the good fortune that supplied him with so able and willing a coadjutor.

The plates were taken with a rapid rectilinear Dallmeyer lens of six inches aperture and fifty-four inches focus. During the course of the work this lens was repolished, and a portion of the work duplicated with a second lens; but allowing for all interruptions, the work that was begun on April 15, 1885, was finished in December 1890, with the result that the whole sky was photographed from the South Pole to − 19° declination. The free area of each plate was five degrees square, more than 600 being required to cover this portion of the heavens once, without any duplication. At first, when plates were rather slow in action, an hour's exposure was given; but this time was subsequently reduced to about thirty minutes. It is instructive to notice that many plates on a first examination had to be rejected, owing to the fainter stars not having impressed themselves on the film, on account of mist, dewing of the objective, or bad definition. "The more thorough examination necessarily made by Prof. Kapteyn in course of measurement, brought to light a good many more plates which it seemed desirable to re-photograph, so that some of the areas have been photographed three, four, and even five times." Such a report will not be very satisfactory reading for those engaged on the "Carte du Ciel."

The measurement was effected in a manner that necessitated very small corrections to the original readings, in order to obtain the approximate star places, referred to the equinox of 1875; indeed, Prof. Kapteyn says that the coordinates read from the instrument might have been entered directly in the catalogue. We can form a tolerably accurate notion of the time occupied in measuring the plates, for it is stated that on good rich plates two assistants could measure 300 to 400 stars in an hour. Probably 200 would represent the average, and since this portion of the catalogue contains 152,598 stars, we have about 750 hours of actual measurement for one complete examination. Such a rapid collection of results needs no comment. The average distribution of the stars throughout the whole area is possibly of greater consequence than the actual number measured. Of course, the number to a square degree varies very much in different parts of the sky. In the sparsest parts, that is, in Galactic Latitude about − 70°, this number falls to 6·28, rather less than in Argelander; but a comparison of *mean* results with other zones gives the following numbers.

Cape Photographic Survey ...	25·43	stars to square degree.
Bonn N. Durchmusterung ...	15·19	,, ,,
Schönfeld	18·21	,, ,,
Thome	56·1	,, ,,

The arrangement of the stars in the catalogue, and the degree of accuracy aimed at, is the same as in the familiar Bonn work, namely one-tenth of a second of time in R.A., and a tenth of a minute of declination. A comparison between the places here given with those of other catalogues shows that the probable error of a photographic determination contrasts most favourably with that derived from other processes. This is clearly shown by the following table.

Authority.		Prob. error in α.	Prob. error in δ.
	° °	s.	"
Argelander ..	− 2 to + 38	± 0·70	± 25·4
Schönfeld	− 2 to − 23	0·38	9·6
Cordova	− 22 to − 32	0·42	13·8
Cape Photog. ...	− 19 to − 38	0·27	2·6
Lalande (1880)...	+ 1 to + 5	0·224	2·4

We do not propose in this place to follow Prof. Kapteyn in his discussion of the magnitudes assigned in the work, and his comparison with the visual magnitudes recorded by other observers. The section is very interesting and likely to lead to much discussion, owing to the curious fact disclosed, that while this catalogue is poorer in number of stars in the poor regions of the sky, it is at the same time richer in the rich regions, than is the catalogue of Schönfeld, from which fact Prof. Kapteyn concludes that the stars in the Milky Way are generally more chemically active than the stars in the other regions of the sky. W. E. P.

NOTES.

REFERRING to our inquiry (p. 488) as to disturbances of terrestrial magnetism during January and February, Dr. C. Chree writes from the Kew Observatory as follows:—"With the exception of some small movements on the 10th, our magnetic curves were very quiet from January 1 to 14; but thereafter there was a disturbed time, lasting over January 15 to 21. The disturbance was greatest from the 15th to the 18th—when it was well marked—less on the 19th and 20th, and still less on the 21st. The 22nd and 23rd were very quiet days. The rest of January was quiet generally, with a few small movements. February was quiet up to the 10th, with the exception of some slight movements on the 5th. From February 11 to 16 there was a moderately disturbed time; on the 20th and 21st there were some smaller movements. It was then quiet to the end of the month. 'Quiet' is, of course, only a relative word; there is seldom a day in which some slight movement, beyond the mere diurnal inequality, is not visible. In the case of the disturbances on January 15–21 and February 11–16, it was rather a case of numerous well-defined oscillations than of sudden comparatively isolated movements of a conspicuous character."

A CONFERENCE of the International Aeronautical Commission opens to-day at Strassburg, and will continue for several days. Among the experiments to be performed during the meeting is the graduation of thermographs down to − 200° C. by means of a jet of liquid air procured by the Linde method. Dr. Hergesell, the president of the conference, will present a report upon the thermometric experiments already referred to in NATURE (p. 470). M. Besançon will send up a balloon of twelve hundred cubic feet capacity, equipped with meteorograms, which it is estimated will attain an altitude of about twenty thousand feet. Several members of the Paris Academy of Sciences have signified their intention to attend the conference.

THE Paris correspondent of the *Times* reports that at Monday's sitting of the Academy of Sciences the question of the French national time was introduced by M. Bouquet de la Grye, the president of the Paris Geographical Society and a member of the Section of Navigation and Geography. The fact was recalled that on February 24 the Chamber of Deputies passed without discussion and on a show of hands a Bill providing that French national time should be advanced by 9 minutes 11 seconds, which was tantamount to the adoption of the meridian of Greenwich by France. The Bureau des Longitudes has, however, sent a protest to the Minister of Education, and the protest has been forwarded to the President of the Senate. M. Bouquet de la Grye asked the Academy to refer the whole question to the joint Sections of Astronomy and Navigation to be reported upon. This motion was supported by M. Janssen and adopted after some explanations from M. Berthelot and M. Bertrand, the two permanent secretaries.

IT is announced that the Russian Government has decided to adopt the metric system.

A FRENCH ironclad launched a few days ago was christened the *Lavoisier*.

PROF. J. E. KEELER has been elected director of the Lick Observatory, in succession to Prof. E. S. Holden.

THE current number of the *Proceedings of the Royal Society* contains an obituary notice of Pasteur by Prof. Percy Frankland, F.R.S.

MR. A. D. BERRINGTON is on the point of retiring from the post of chief inspector of fisheries and assistant secretary to the Board of Trade. Among the fishery inspectors who preceded Mr. Berrington were Mr. Frank Buckland and Prof. Huxley.

THE Public Buildings Expenses Bill, providing 2,250,000*l.* for new public buildings in London, passed through Committee of the House of Commons on Tuesday. Included in the expenditure authorised by the Bill is a grant of 800,000*l.* for buildings in connection with the Science and Art Museum at South Kensington.

A SWEDISH scientific expedition to Klondike, conducted by Dr. Nordenskiöld, arranged to leave Stockholm on March 23. Dr. Nordenskiöld will be accompanied by Dr. Gunnar Andersson, professor at the Stockholm High School, and four other persons. The expedition is expected to be absent about two years. Immediately after its return the expedition will make known the results, not only in Sweden, but also to scientific societies in other countries.

IT is reported that Herr J. Stadling, who accompanied Herr Andrée's expedition to Spitsbergen in 1896, has been appointed by the Swedish Anthropological and Geographical Society to undertake a search through Siberia in order to make inquiries as to the fate of Herr Andrée's balloon expedition. For this purpose Herr Stadling has received the Vega stipendium from the Society. He will start with a companion from Stockholm early in April, and the journey will last probably until January next.

A COMMITTEE has been appointed by the Home Secretary to inquire into the extent to which water gas and other gases containing a large proportion of carbon monoxide are being manufactured and used for heating, lighting and other purposes, and the dangers which may attend such manufacture and use. The committee is composed of Lord Belper (chairman), Mr. H. H. Cunynghame, Dr. Parsons, Dr. Haldane, and Prof. Ramsay; with Mr. J. Pedder, of the Home Office, as secretary.

AT the meeting of the Manchester Literary and Philosophical Society on Tuesday, the President presented the Wilde medal for 1898 to Sir Joseph Dalton Hooker, G.C.S.I., F.R.S.; the Dalton medal to Dr. Edward Schunck, F.R.S.; and the Wilde premium for 1898 to Mr. John Butterworth. The Wilde lecture, "On the Physical Basis of Psychical Events," was afterwards delivered by Prof. Michael Foster.

THE British Association Committee of the Ethnographical Survey is desirous to obtain the services of qualified observers in numerous parts of the United Kingdom, for the purpose of inquiring into all or any of the following subjects: (1) physical types of the inhabitants; (2) current traditions and beliefs; (3) peculiarities of dialect; (4) monuments and other remains of ancient culture; (5) historical evidence as to continuity of race.

Communications should be addressed to Mr. E. Sidney Hartland, hon. sec. Ethnographical Survey Committee, British Association, Burlington House, W.

Prof. N. E. Hansen, professor of horticulture at Brookings, South Dakota, who was sent to Eastern Europe and Asia to secure new seeds and plants for the Agricultural Department of the United States, is (says *Science*) now preparing his report for publication, after an extended trip through Eastern Russia, Trans-Caucasia, Russian Turkestan, Western China, and Siberia. Many promising varieties were obtained, and about three car-loads of seed will be distributed to State experiment stations. These seeds, it is expected, will be chiefly of value in the arid regions, the purpose of Prof. Hansen's trip being to obtain such as were distinguished for resistance to drought and heat.

The following are among the lecture arrangements at the Royal Institution after Easter:—The Right Hon. Lord Rayleigh, F.R.S., three lectures on natural philosophy; Dr. E. E. Klein, two lectures on modern methods and their achievements in bacteriology; Mr. J. A. Thomson, two lectures on the biology of Spring. The Friday evening meetings of the members will be resumed on April 22, when Mr. W. H. M. Christie, C.B., the Astronomer Royal, will deliver a discourse on the recent eclipse; succeeding discourses will probably be given by Prof. A. Gray, Mr. E. A. Minchin, Prof. W. A. Tilden, the Right Hon. D. H. Madden, Lieut.-General the Hon. Sir A. Clarke, Prof. W. M. Flinders Petrie, the Right Hon. Lord Rayleigh, and other gentlemen.

Science announces that Prof. W. A. Rogers died at Waterville, Maine, on March 1, aged sixty-one years. He was assistant professor of astronomy in the observatory of Harvard University from 1875 until 1886, when he accepted a call to the professorship of physics and astronomy at Colby University. He had expected to enter on a professorship at Alfred University, N.Y., on April 1. Prof. Rogers was a member of the United States National Academy, and a past vice-president of the American Association for the Advancement of Science. He made important contributions to astronomy and physics, especially to the technique of measurement.

Storms of more than ordinary severity were experienced on our coasts last week, and were accompanied by a good deal of snow in many districts. A cyclonic disturbance, which arrived from the Atlantic on March 23, crossed the northern portion of Scotland, travelling in a south-easterly direction; and, after continuing its course down the east coast of England, the central area of the disturbance crossed the North Sea, and eventually passed over Germany. Owing to the prevalence of anticyclonic conditions over Scandinavia, the track followed by the storm was somewhat unusual, and its progress was very slow, while the area of high barometric pressure advancing in the rear of the disturbance gained additional energy. It was particularly to this last feature that the storm owed its chief violence; the gales experienced from the 23rd to the 27th belonged to the rear segment of the storm-area, and were wholly from the north and north-east. They have proved very disastrous on our coasts, and have also wrought considerable damage over the inland parts of the country. The general characteristics of the disturbance, both in its cause and effect, closely resembled those of the storm which occurred at the end of last November.

The report of the Council of the Scottish Geographical Society was presented at a general meeting held on March 23. After referring to the general reports of the meteorological stations, the Council state that, as intimated in the last report, the observations at the intermediate station on Ben Nevis, at a height of 2322 feet, were resumed last summer. The observations form a very complete series, thanks to the great enthusiasm and self-denial of the observers, Mr. T. S. Muir and Mr. A. Drysdale, aided by several valuable self-recording instruments. From the varying cyclonic and anti-cyclonic types of weather which prevailed during the ten weeks of observation—July 19 to end of September 1897—the Society is now in possession of simultaneous hourly observations from the three observatories on Ben Nevis, which are really the indispensable data in investigating the problems relating to the vertical gradients of the temperature, pressure, and humidity of the atmosphere and its movements. The work of making daily maps showing the rainfall at 120 stations well distributed over Scotland is in progress; and to these are being added the figures showing the hours of the occurrence of fog at the Scottish lighthouses. The large series of maps, in illustration of the mean monthly and annual atmospheric pressure and temperature of the British Islands, is well in hand. The maps of isothermals are finished, and the maps of isobars will be on the stone in a few days, and no time will be lost in issuing the number to members. The Council announced a Diamond Jubilee donation of 100*l.* from one of the members, of which 50*l.* is for discussion of separate parts of the work of the Ben Nevis observatories, and 50*l.* in furtherance of the Society's work. It was also announced that the late Hon. Ralph Abercromby bequeathed a legacy of 100*l.* to the Society.

Das Wetter of February reproduces a lecture, recently delivered by Dr. G. Hellmann, on the interesting question of mild winters. The facts are based upon the temperature observations at Berlin, for which place observations are available since the early part of the previous century, and the subject is divided into three parts: (1) the frequency and succession of mild winters, (2) their general character, and (3) what kind of summer weather may be expected after a mild winter. For the purpose of this investigation, the author defines a mild winter as one in which the mean temperature of December and January is above the average, and in which the sum of the deviations in both months amounts at least to 2° C. A table giving the monthly deviations for November to August shows that since 1720 there have been forty-eight mild winters in Berlin, that they are never isolated, but occur in groups of two or three years, and especially after a long period of colder winters. The intervals between two groups of mild winters vary from nine to fourteen years. With regard to the character of mild winters, the table shows clearly that they are usually of long duration. The chances are 79 to 21 that after a mild winter, February will also have a high mean temperature. Another characteristic of mild winters is that the greatest deviations of temperature usually occur in January. Whether a mild winter will be damp or dry depends chiefly upon the distribution of atmospheric pressure; the present winter is of the mild and dry type. The general distribution of pressure between December 5, 1897, and January 29 last, is illustrated by weekly charts. With respect to the influence of mild winters upon the subsequent weather, and especially of the summer, if July and August be taken together as representing the summer, it is found that the chances are 44 per cent. that a warm summer will follow a moderately mild winter; while after a very mild winter, the chances of a warm summer amount to 68 per cent. The cases of mild *dry* winters, such as the present, are rare; if the deficient rainfall is not compensated during spring time the summer is likely to be wet, and consequently cool.

The *British Medical Journal* for March 19 contains an important paper by Dr. Luigi Sambon, on the "Etiology of Sunstroke." Dr. Sambon adopts what at first appears a somewhat startling theory, namely, that sunstroke is not due to excessive heat or exposure to the sun, but is an infectious disease due to a specific organism. The author's case rests on three lines of argument. He begins by showing that excessive heat does not produce the disease; stokers, oven-cleaners, miners, and iron-workers are exposed to temperatures higher than those of any known climate, without ever contracting the malady. The Assam tea-planters and the closely-shaven Chinese are constantly exposed to the hottest sun, and are equally exempt. Dr. Sambon next discusses the geographical distribution of the disease, and proves that the areas in which it is endemic are strictly defined. It is very common in the low-lying regions of the Eastern United States, between the Appalachians and the Atlantic; it is unknown in Europe; it extends along the Nile Valley, Red Sea, and Persian Gulf; it prevails in the Indo-Gangetic alluvial plain, but not on the adjacent Indian highlands. Another peculiar feature of the disease explicable on the infection theory is the occurrence of epidemics, which may decimate hospital wards and not affect men exposed to greater heat and sun. Dr. Sambon concludes that the distribution, etiology, morbid anatomy, and epidemic character of the disease together demonstrate its organic origin. The specific organism has not been detected, but the author believes it lives in the superficial layers of the soil, and is conveyed to the lungs or alimentary canal by dust.

A PRELIMINARY statement just issued by the Canadian Geological Survey, in advance of the detailed annual report, shows that the gold produced by the Dominion in 1897 amounted to a value of 1,238,000*l*. This means that the Canadian gold output increased by 122·6 per cent. in a single year. In 1896 gold only formed 12·30 per cent. of the total mineral produce of the country (reckoning by value), while coal and building material provided 31·94 per cent. and 15·72 per cent. respectively. In 1897 gold rose to the second place on the list, with a percentage of 21·50, coal and building material being credited with percentages of 25·31 and 12·50 respectively.

A SHIP model experiment tank is being built at Washington by the United States Navy, at a cost of about 100,000 dollars. From a description in the *New York Engineer*, we learn that the tank will be a concrete lined basin, surmounted by a brick building 500 feet long by 50 feet wide, the basin itself being 47 feet long by 43 feet wide by 14 feet deep. On each side of the basin, for its whole length, will be iron rails supporting the ends of a carriage spanning the basin, this carriage being propelled along the tank with the model and measuring dynamometer attached, the model being guided along while still floating freely in the water. The carriage, with all dependent on it, is driven along the tank by four electric motors, taking current from a wire by means of trolley poles. The degree of resistance encountered by the model in passing through the water, also the time taken and the distance traversed, are all recorded diagrammatically and by electrical means. Hydraulic brake cylinders on each side of the carriage provide for stopping the carriage when run at very high speeds. The models experimented with will be one-twentieth of the actual size of the vessels, the model for a 400-foot ship being thus 20 feet long. Tests will be made with models for merchant vessels as well as war-ships, and special experiments will be conducted as to the effects of propellers of different sizes and shapes, and the effects of the shape of the after-end of vessels upon the efficiency of the propeller.

MR. J. C. GOUDIE contributes the following interesting observations to the February number of the *Victorian Naturalist*, the journal and magazine of the Field Naturalists' Club of Victoria:—"A small species of ant, commonly distributed in the Mallee, has a curious habit of keeping in close confinement a rather large mealy aphis, which feeds on the stems of young eucalypts. Round and over these aphides the ants construct a domed covering of particles of bark, grass, &c., which serves the double purpose of imprisoning the aphides and excluding other ants. Some of these coverings appear to be entirely closed, while others have an opening left in the edge; this doorway is, however, constantly guarded by a pair of ants, which continually move about in the open space, and seem much impressed with the importance of the duty assigned to them. Each enclosure contains generally from three to a dozen aphides, and about the same number of ants. Upon making a breach in some of these structures, for the purpose of observation, I have noticed that many of the 'live stock' were immediately seized by the ants and forcibly removed to a place of safety. The ant under notice is about a quarter of an inch in length, and is of a uniform dark reddish-brown colour, and forms its ordinary habitation under logs, or in old rotten stumps, and sometimes in the ground. Several other species of ants are very assiduous in their attendance on the various aphides, Tetigonidæ, and coccids, but the above is the only kind I have noticed that uses such extraordinary means to secure a monopoly of the much-prized 'honey-dew.'"

THE *Journal* of the Society of Arts for March 4 contains the account of a lecture, by Captain Baden-Powell, on "Kites," in which the advantages and disadvantages of different forms and combinations of kites, as well as their various uses for lifting, traction, reconnoitring, and other practical purposes are fully discussed.

KOENIGS and Lie have proved that if the poles are taken of an arbitrary plane with respect to the conics of a Steiner's surface, their locus is another Steiner's surface. A new proof of this theorem is given by Prof. A. Brambilla, in the *Rendiconto* of the Naples Academy, who makes use of symbolic notation enabling him to introduce considerable symmetry into the equations.

SOME doubt has existed as to who was the first to discover the microscopic Foraminifera, and to apply the microscope to the investigation of rock-structure. From a communication by Prof. Giovanni Capellini to the *Rendiconto* of the Bologna Academy, it would appear that on March 3, 1711, a paper, entitled *De variis arenis*, was communicated to that Academy by Jacopo Bartolomeo Beccari, of Bologna, thus indicating that priority must be awarded to Beccari.

ACCORDING to the views communicated to the Bologna Academy by Prof. Federico Delpino, it would appear that the lesser celandine (*Ranunculus Ficaria*) of our English hedgerows is to be regarded as the dwarf form of a dimorphic plant, whose dimorphism is of the kind known as *gynodiœcism*. Prof. Delpino contends that the hermaphrodite form is the larger plant, so common on the Riviera, known as *Ficaria calthæfolia*, and that our *Ficaria ranunculoides*, Moench, is the smaller female form of the same species. This theory accounts for the facility with which the celandine is propagated agamically, and the sterility of its pollen.

A REPORT on the colour of water by M. Ad. Kemna, of the Antwerp Waterworks Company, has been recently reprinted from the *Bulletin de la Société belge de Géologie*, and is published by Polleunis and Ceuterick, of Brussels. In it the views of various writers, from Arago downwards, on the physical, chemical, and organic causes of the different colours of different waters, are summarised, M. Spring's theories being dealt with at considerable length. M. Kemna indicates the practical bearing of these investigations on the testing of water supplies of towns, and describes different methods of applying tests. Of these, the tests known as the Hazen tests, and due to Mr. Allen Hazen, of Massachusetts, find most favour with the author.

Attention has several times been called in Nature to the various optical illusions by which one of two equal straight lines can be made to look larger than the other by drawing them in particular positions, or a series of parallel lines can be made to look askew by drawing slanting lines across them. A very full and detailed account of these illusions is now given, by Herr Wilhelm Wundt, in a paper reprinted from the *Abhandlungen der k. Sächs. Gesellschaft der Wissenschaften*, and published by B. G. Teubner in Leipzig. The paper is illustrated by sixty-five woodcuts, showing all the principal and many less-known appearances of this class, and Herr Wundt discusses at considerable length the causes of these subjective phenomena, whose existence appears to have been first made known by J. Oppel in 1854.

Sunshine recorders and their indications are often regarded with suspicion by meteorologists; and not without cause, for it can hardly be claimed that any sunshine recorder in use is a satisfactory physical instrument. In the current number of the *Quarterly Journal* of the Royal Meteorological Society, Mr. R. H. Curtis reports the results of a comparison between the sunshine records obtained simultaneously from a Campbell-Stokes burning recorder, and from a Jordan photographic recorder. The comparison indicates that the Campbell-Stokes instrument gives records which can be measured with a fair degree of accuracy by different persons, and are not liable to as much uncertainty as the records of the Jordan instrument. Contrary to the belief of many observers the photographic records were not, upon the whole, in excess of the records obtained with the Campbell-Stokes instrument.

In the *Free Museum of Science and Art* (Philadelphia) for December, Dr. Brinton draws attention to a discovery among the ancient marbles of the Louvre of an admirable representation of the wearing of the murmex. It is figure No. 68 in the Salle des Caryatides. The discovery, says Dr. Brinton, removes all doubt of the correctness of his identification of the so-called bow-puller with the murmex. The bow-puller is the name generally given to a bronze object found in museums. The "collections and publications" section of this very useful bulletin is exceedingly good, and we are tempted to hope that our own museums may some day call forth the interest that is evidently felt by Americans in theirs.

The *Reliquary and Illustrated Archæologist* for January last is almost entirely anthropological in interest. Mr. Leader Scott's account of the Gallic necropolis in Italy, discovered by Conte Giampieri Carletti on a tract of land at the foot of an indentation of Mount Montefortino, near Arcevia, is particularly interesting; while the next three articles—on some old-fashioned contrivances in Lakeland, by Mr. Swainson Cowper, on the modern use of bone skates, by Mr. Henry Balfour, and on beer and labour tallies, by Mr. Edward Lovett—lead us to the domestic antiquities of our own country, which are all too frequently neglected. The dairy appliances described, *inter alia*, by Mr. Cowper are very interesting, and we hope he will go on to give us sufficient material to work out the evolution of farm implements.

The *American Anthropologist* for November and December last contains a specially good article on the aborigines of Formosa and the Liu-kiu islands, by Mr. Albrecht Wirth. The aborigines who cling to the savage state are short of stature, the majority being under 5 feet 6 inches. They have broad faces with low brows, straight and high noses wide at the nostrils, and lips not so thick even as those of the Malays. The subject of trephining in Mexico is dealt with by Carl Lumholtz and A. Hrdlicka, who give some valuable additional notes upon this interesting subject. Mr. Lewis W. Gunckel analyses the deities of Mayan inscriptions, an obscure subject not perhaps of sufficient interest to attract much general attention.

The Geologists' Association have arranged an Easter excursion to Bridport and Weymouth, under the direction of Prof. J. F. Blake, Mr. W. H. Hudleston, F.R.S., and Mr. S. S. Buckman. The party will leave Paddington Station on Thursday, April 7, and will return on Tuesday, April 12.

Prof. H. G. Seeley, F.R.S., will begin the summer course of lecture-excursions with the London Geological Field Class on Saturday, April 23. The subject of the series will be "The Physical Geography and Geology of the Thames and its Tributaries." This is the thirteenth annual course. Mr. R. H. Bentley, 43 Gloucester Road, South Hornsey, N., is the hon. secretary to this class, which provides a systematic course of geological teaching in the open country.

The Society for the Protection of Birds has issued Part ii. of the Educational Series of leaflets, edited by Mr. H. E. Dresser. Thirteen leaflets are bound up in this part, and each contains interesting notes on the appearance, characteristics and habits of British birds. The information will induce the reader to observe bird-life with a sympathetic eye, and will thus further the Society's objects.

The second number of the *Science Abstracts*, issued under the direction of the Institution of Electrical Engineers and the Physical Society, has just been issued. Additions have been made to the list of journals from which papers are abstracted, and it is proposed to considerably enlarge the monthly parts as time goes on. The staff of abstractors is also being increased. The value of *Science Abstracts* to the physicist and the electrical engineer is very great, and no student of physical science who wishes to keep in touch with the world of investigation can afford to neglect so serviceable a publication.

We have received *Natural History Transactions*, vol. xiii. part 2, published by the Natural History Society of Northumberland, Durham, and Newcastle-upon-Tyne, an institution which has recently completed its jubilee. The Society promotes an important museum, and detailed enumeration is given of the mammals, birds, and miscellaneous objects to the collections. Prof. G. S. Brady, F.R.S., has a long paper on the British species of Entomostraca belonging to Daphnia and other allied genera. A paper on the "Life History of Coal" seems to take up a great deal of valuable space, and suggests curtailment. There is much interesting information conveyed in the reports of the committees. Lord Armstrong has apparently been a munificent supporter of the Society. We are of opinion, though of course it may not fall in with local necessities, that much of the matter contained in this and similar publications might perhaps be condensed and printed in appendix form, so as to bring the papers and record of actual scientific progress more into prominence.—The *Proceedings* of the Bristol Naturalists' Society, vol. viii. part 2, has also reached us. There are several useful contributions in this nicely-printed publication, covering many branches of science. An interesting paper appears on the "Chemistry of Colliery Explosions," by Mr. Donald Stuart, which is supplemented by a plan of Timsbury Collieries, in Somersetshire, exhibiting the workings traversed by an explosion. Noticeable also is a paper, by Mr. S. S. Buckman and Mr. E. Wilson, on the "Geological Structure of the Upper Portion o Dundry Hill."

The additions to the Zoological Society's Gardens during the past week include a Herring Gull (*Larus argentatus*), British, presented by Mrs. Hovell; three Bactrian Camels (*Camelus bactrianus*, ♀ ♀ ♀) from Central Asia, two Yaks (*Poëphagus grunniens*, ♀ and juv.) from Tibet, a Beisa Antelope (*Oryx beisa*, ♂) from North-east Africa, a Burchell's Zebra (*Equus burchelli*, ♀) from South Africa, a Weka Rail (*Ocydromus australis*) from New Zealand, four Radiated Tortoises (*Testudo radiata*) from Madagascar, a Galapagan Tortoise (*Testudo galapagensis*) from the Galapagos Islands, deposited.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN APRIL 1898 :—

April 3. Pallas 15′ south of *o* Eridani (mag. 4·1).
5-15. Mercury well visible in the evenings near Venus.
9. Juno (mag. 8·7) in opposition to the sun.
10. 13h. Mercury at greatest elongation (19° 23′ E.).
10. 14h. 38m. to 15h. 8m. A Ophiuchi (mag. 4·7) occulted by the moon.
10. Saturn. Outer minor axis of outer ring = 18″·14.
14. 5h. 51m. to 8h. 26m. Transit of Jupiter's Sat. III.
15. Venus. Illuminated portion of disc = 0·968.
15. Mars ,, ,, ,, = 0·953.
16. 9h. 4m. Minimum of β Persei (Algol).
18. Mercury and Venus in conjunction (Mercury 3° 20′ N.).
19-20. Meteoric shower from near α Lyra (radiant 270° + 32°).
21. 9h. 11m. to 11h. 49m. Transit of Jupiter's Sat. III.
21. 15h. Mercury in conjunction with moon (Mercury 2° 2′ S.).
27. 6h. 41m. to 7h. 44m. 79 Geminorum (mag. 6·5) occulted by moon.
28. 12h. 34m. to 15h. 15m. Transit of Jupiter's Sat. III.
29. 13h. 1m. to 13h. 15h. ξ Leonis (mag. 5·2) occulted by moon.

FAVOURABLE APPARITION OF MERCURY.—The most convenient period in 1898 for observing Mercury will be during the fortnight from April 5 to 18, when the planet will become visible about an hour after sunset above the W. by N. horizon. He will reach his greatest eastern elongation on the morning of April 11, and will set on several evenings at about this time, a little more than two hours after the sun. Fortunately, at this special period, the planet will be situated within a few degrees of Venus, and the latter will form a brilliant guide to the position of Mercury. On April 5 Mercury will be apparently 6 degrees above Venus, and on ensuing nights the interval decreases until on April 18 the two objects will be in conjunction, Mercury being about 3° 20′ N. of Venus. Mercury will then appear on the north-west side of Venus, but is likely to be much fainter than before elongation, as he rapidly loses brightness owing to the crescent-phase which his disc assumes. The following are the times of setting of the sun, Mercury and Venus, and the intervals at which Mercury sets after the sun :—

Date 1898.	Sun sets.	Mercury sets.	Venus sets.	Mercury sets after sun.
	h. m.	h. m.	h. m.	h. m.
April 5	6 38	8 28	7 45	1 50
6	6 40	8 33	7 48	1 53
7	6 41	8 37	7 51	1 56
8	6 43	8 42	7 54	1 59
9	6 44	8 46	7 58	2 2
10	6 45	8 48	8 1	2 3
11	6 46	8 49	8 4	2 3
12	6 48	8 51	8 7	2 3
13	6 50	8 52	8 10	2 2
14	6 51	8 53	8 14	2 2
15	6 53	8 53	8 17	2 0
16	6 55	8 52	8 20	1 57
17	6 57	8 51	8 24	1 54
18	6 59	8 48	8 27	1 49

The conjunction of Mercury and Venus on April 18, at about 5h., does not appear to be mentioned in the *Nautical Almanac*.

COMET PERRINE.—Dr. F. Ristenpart has calculated the elements and ephemeris of this comet from the observations made on March 19, 21 and 22. These, as given in Circular No. 3 from Kiel, are as follows :—

Elements.

T = 1898 March 18·501. Berlin Mean Time.

$$\left.\begin{aligned}\omega &= 48^\circ\ 47'\cdot1\\ \Omega &= 263\ \ 16\cdot4\\ i &= 72\ \ 44\cdot7\end{aligned}\right\}\ 1898\cdot0$$

$$\log q = 0\cdot04316$$

Ephemeris for 12h. Berlin Mean Time.

1898.	α	δ	log Δ	Br.
	h. m. s.	° ′		
March 31 ...	22 3 0	+28 24·8	0·2019	1·00
April 2 ...	11 30	30 22·0		
4 ...	20 14	32 16·4	0·2054	0·99
6 ...	29 12	34 7·8		
8 ...	22 38 24	+35 65·0	0·2110	0·89

We may mention that the elements calculated by Messrs. Hussey and Perrine are almost identical with those given above.

At the time of this comet's discovery its diameter was 2′, with a strong condensation, and a tail of length equal to 1°. It was then of the 7th magnitude.

TWO NEW VARIABLE STARS OF SHORT PERIOD.—Herren G. Müller and P. Kempf contribute some interesting data to the current number (No. 3483) of the *Astronomische Nachrichten*, relative to the two new variables of short period which were originally discovered during the series of zone observations for the second part of the Potsdam Photometric Durchmusterung. These two stars are BD + 20°·4200 and BD + 28°·3460, or, as they have been named, U Vulpeculæ and ST Cygni respectively.

The first of these stars, whose position for 1900 is R.A. 19h. 32m. 15s., declination + 20° 6′·6, has a period of nearly eight days, the light curve varying from mag. 6·9 or 7·0 at maximum to 7·6 at minimum ; the epoch for the calculation of the maxima being 1897 October 2·47 Greenwich mean time. The light curve shows small secondary variations both in the ascending and descending portions, the rise to maximum and fall to minimum occupying equal intervals of time.

The second variable, whose position for 1900 is R.A. 19h. 40m. 49s., declination + 29° 1′·2, has a period of 3·844 days, the magnitudes at maximum and minimum being 6·6 and 7·4 respectively. The dates of maxima can be calculated from the epoch (maximum) 1897 October 4·66 Greenwich mean time + 3·844 E. In the case of this star the curves on either side maximum are not equal, but the rise to maximum comprises less time than the fall to minimum. The former occupies only 0·9 days, while the latter takes 2·9 days. The curve is described as similar to δ Cephei. The observations suggest that on the downward side of the curve, 1·75 days after the maximum, the light becomes stationary for a short period of time, afterwards decreasing to the next minimum.

VARIABLES AND THEIR COMPARISON STARS.—Variable star observers may be glad to know that Prof. E. C. Pickering is able to furnish the photometric magnitudes of a great many comparison stars for long-period variables, and that he will communicate the information in advance of publication should any one require it (*Harvard College Observatory Circular*, No. 27). Sequences of comparison stars have been selected for about one hundred variables, stars brighter than the tenth magnitude having been measured on at least three nights with the meridian photometer, and those from the eleventh to the thirteenth magnitude on two nights with the photometer having achromatic prisms. Observations are already completed for the following stars :—T Andromedæ, T Cassiopeiæ, R Andromedæ, S Ceti, S Cassiopeiæ, R Piscium, R Arietis, T Persei, *o* Ceti, S Persei, R Ceti, U Ceti, R Tauri, S Tauri, R Aurigæ, U Orionis, R Lyncis, R Geminorum, S Canis Minoris, R Cancri, S Hydræ, T Hydræ, R Ursæ Majoris, X Virginis, R Comæ, T Virginis, Y Virginis, T Ursæ Majoris, R Virginis, S Ursæ Majoris, U Virginis, R Hydræ, S Böotis, R Camelopardali, U Herculis, W Herculis, R Ursæ Minoris, R Draconis, χ Cygni, S Cygni, R Delphini, U Cygni, V Cygni, T Aquarii, T Cephei, S Cephei, SS Cygni, S Aquarii, R Pegasi, S Pegasi, R Aquarii, and R Cassiopeiæ.

Prof. Pickering adds that the brightness of each of these variables is being determined monthly by Argelander's method, and it would be a good thing if other observers would reduce their observations to the same scale of magnitudes, as then the desired uniformity in results would be obtained.

The variability of the star in Aquila, R.A. 19h. 33·3m., Decl. + 11° 29′ (1900), announced recently by the Rev. T. D. Anderson, has been corroborated by an examination of the Harvard photographs. Measures of fifty-seven negatives gave the maximum brightness 9·2, and minimum less than 12·9. The variations can be closely represented by the formula J.D. 2411550 + 330 E.

CONCAVE GRATINGS FOR STELLAR PHOTOGRAPHY.—Some experiments have been carried on quite recently at the Johns Hopkins University to investigate the value of the use of concave gratings for stellar spectroscopy, and the results obtained bid fair for further trials (*Astrophysical Journal*, vol. vii. No. 3, March). The methods originally suggested by Prof. Rowland have been developed; Dr. Poor has derived the formulæ, and directed the construction of the apparatus, while Mr. Alfred Mitchell has made the experiments and photographs. The method finally adopted was the direct one, the grating being the objective and spectroscope combined; the light from the star was thus reflected directly from the grating to the photographic plate. The best position for general work was found to be that in which the centre of the photographic plate falls on the axis of the grating. From the simplified general equation

$$r = \frac{\rho}{1 + \cos \nu}$$

in which ρ is the radius of curvature of the grating, R and v the spherical coordinates of the light source, and r and μ those of the curve on which the spectra are brought to a focus (R being ∞ and $\mu = 0$), it was found that those parts of the spectra where $\cos \mu$ could be assumed equal to unity, were brought to a focus *on a circle whose radius is given by the above equation*. The equation really represents a parabola, but within certain limits the spectrum may be considered normal. For a grating of medium dispersion, the entire spectrum will be practically normal; but with one giving larger dispersion, as a Rowland 21-foot, the scales of the middle and end differ by one and one-half parts in a thousand at a distance of 3° from the axis. It is *necessary*, therefore, that parabolic curved photographic plates must be used, but within certain limits they may be circular. In the experiments a small Rowland concave grating, of 15,000 lines to the inch, radius of curvature one metre, and ruled surface 1 × 2 inches, was employed, the photographic plates being bent to the proper radius. The spectra of Sirius, Capella, and Rigel obtained were 5 cm. long, and from 0·1 mm. to 1·5 mm. broad, and showed many lines.

Thus with an exposure of forty minutes, the spectrum of Sirius showed "16 hydrogen, H and K lines, and 15 other distinct fine lines." Capella, with forty minutes' exposure, gave F.G.h.H.K., and about fifty fine lines. It may be mentioned that these experiments were made on the fifth floor of the Physical Laboratory, "subject to the jar of street-cars and city traffic, as well as to dust and to the glare of electric lights," so that the results were not obtained under the *best* conditions.

A CATALOGUE OF 636 STARS.—No. 4 of the *Mittheilungen der Hamburger Sternwarte* contains a catalogue of stars observed by Herr W. Luther in the years 1885–92 with the meridian circle of the Hamburg Observatory. The observations in R.A. were made after the eye and ear method: those for declination by bringing the stars between two horizontal wires. The positions have all been reduced to the year 1885, and a comparison is made with the catalogue of the Astronomische Gessellschaft Zonen.

THE PREPARATION OF MARINE ANIMALS AND PLANTS AS TRANSPARENT LANTERN-SLIDES.

AT the request of the editor of NATURE, I give an abridged account of my essay in the volume of original researches published to commemorate the establishment of the Sheffield University College by Royal Charter in 1897. I shall confine myself mainly to the animals shown in the reproductions from four of the series of photographs taken by Mr. J. E. Atkinson, of our College, from some of my slides. Though on the whole these reproductions show the general facts fairly well, much of the minute detail is unavoidably lost, which is quite distinct when the mounted animals or photographs are somewhat magnified.

It is about eleven years ago that I first attempted to prepare lantern-slides with marine animals. At first I did not mount them in balsam, but very soon found that this is in almost every case not only desirable but even essential, since they so readily become mouldy, sometimes are attacked by mites, and are often far too opaque. Some also scale off from the glass and break to pieces, unless mounted. The success of the preparations depends almost as much on the proper mounting with balsam as on anything else, and sometimes the only way to get excellent results is to mount several, and pick out the best, which perhaps cannot be known until the specimens are finally mounted in balsam.

The methods necessary in mounting vary greatly in the case of different animals. Often little else is wanted than to arrange them properly on a lantern-glass, so that they touch it more or less completely all over their under surface, and then to drain and dry them. Many readily adhere round the drying edges, before the central parts are dry; and being thus fixed, they do not shrink laterally on further drying, but merely become thinner. On finally drying completely they may partially scale off, and it may be desirable to gum them down in one or more places, lest they should become loose when mounted in the balsam. There are a few animals that will not adhere at all to the glass, and yet shrink greatly. This circumstance has so far prevented me from making satisfactory slides of *Actiniæ*. I have succeeded with every other group.

Few animals are more easy to prepare than small flat fish like soles and dabs, 2 or 2½ inches long. These are killed by putting them into dilute alcohol, and arranged on the glass as soon as dead, whilst still limp. The chief matter is to arrange out the fins neatly. These soon dry, and adhere well; but in order that the side near the glass may keep flat, it is desirable on further drying to adopt a plan which I find most useful in many other cases. Very few, if any, animals will adhere in an objectionable manner to thin paper soaked with bees-wax, and, having laid such over the animal, pressure can be applied. What is wanted is that this pressure should be fairly uniform, and not merely on the thick parts. This is easily done by having a stout lantern-glass covered by two or three thicknesses of fine thin flannel, which is pressed down by a smaller or larger weight, so regulated as not to crush or distort the animal, but rather to retain as much as possible the natural shape and show the internal structure. The animal then dries through this flannel, and at the same time keeps sufficiently flat on the glass. Finally, any specially high parts can be pressed down by using a flat glass without flannel and a heavier weight.

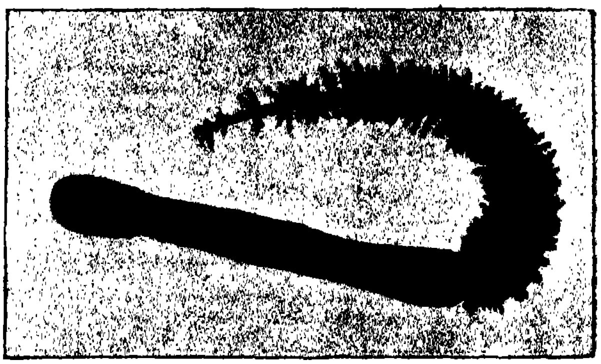

FIG. 1.—*Priapulus* in natural state.

A considerable variety of marine worms can be made into most excellent transparent slides, showing not only their general shape and colour, but also much of their internal structure. *Sabella* may be named as a specially good example. Such animals should be killed by keeping them for a short time in dilute alcohol. The aim should be to dry them before partial decomposition sets in and destroys the small blood-vessels. If all goes on well it is possible to dry and permanently preserve such worms as *Nereis*, so as to show not only the chief blood-vessels but even the smallest branches, and the blood may retain its red colour for years without any apparent change.

As an example of an animal mounted without staining, I give in Fig. 1 a reproduction from *Priapulus*. It should be killed by putting it into fresh water, and left in it so long that the body just begins to get limp. It can then be easily arranged on the glass, and adheres fairly well without lateral contraction. If mounted at once or previously kept in alcohol the body is too hard and will not adhere to the glass, and on drying contracts so much laterally as to become very unlike the living animal. The internal anatomy and general structure are best seen by cutting the animal open from end to end, and staining the whole with Beale's carmine or Kleinberg's hæmatoxylin. When thus prepared, the muscular structure of the body-wall and the general internal anatomy are seen to great perfection.

I have not yet succeeded in preparing specimens of *Arenicola* when in their natural condition, so as to show their internal structure well, but have made some most excellent preparations by carefully cutting the animal open from end to end, spreading it out on the glass, and displacing the intestine and its appendages so as to be quite clear of the body, but yet to show the numerous blood-vessels passing to the lateral branchiæ from the main trunks along the intestine, which, however, are imperfectly seen in Fig. 2, which I give as an illustration of what may be done by partial dissection. Of their kind no preparations could be more satisfactory than some thus made, since the general anatomy is seen to great perfection, and the colour of the blood has remained unchanged for years, though in other cases, from some unexplained cause, it quickly turned brown.

It was the desire to preserve some of the beautiful Nudibranchs that led me to mount animals on slides. The lovely purple *Eolis* quickly loses its colour in alcohol. It should be killed in dilute alcohol, but kept in it a very short time, and then arranged on the glass and nearly dried. A strong solution of gum should then be placed over it, and the whole kept damp over diluted alcohol, to enable the gum to soak well into the animal, so as to protect the pigment from the balsam, in which it is soluble. I have specimens which have been mounted for more than seven years without showing any further change than the loss of a bluish tint, which occurs almost at once.

Most excellent transparent slides may be made with the so-called spider crabs, and these sometimes show well the manner in which they are covered with a growth of sertularians, sponges, ascidians, &c. The animal is properly arranged on the glass, and at first gentle, and afterwards stronger, pressure applied, using waxed paper and glass covered with flannel; by which means the whole may be pressed flat without material distortion. The body and legs may indeed be made a little wider than natural, but this is to a great extent counteracted by lateral shrinking. At all events the general results are extremely good, and the muscles in the legs well seen.

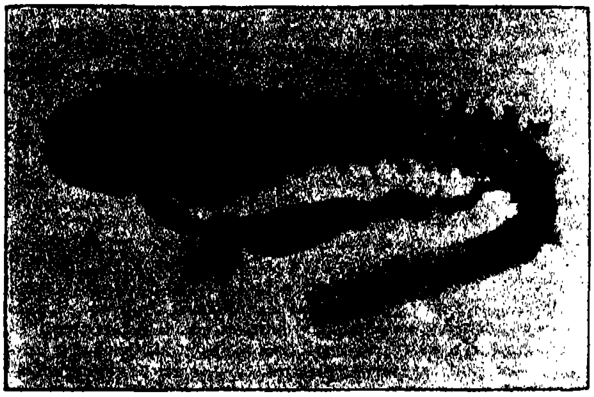

FIG. 2.—*Arenicola* partly dissected.

Various species of Mollusca can be prepared so as to show their general anatomy by dissolving away the shell with hydrochloric acid in diluted alcohol. The organic matter of the shell retains the natural form, and shows the attachment of the various parts of the animal, which may be stained or not according to circumstances. Judging from what I have done, it will be possible to prepare instructive slides from the shells alone of some species, by dissolving away the carbonate of lime and mounting the membranous residue, which retains the natural form and much of the colour.

When first I attempted to mount Medusæ as lantern-slides, I looked upon them as most unpromising, and never imagined that it would be possible to prepare such specimens as I now possess. The first step must be to dissolve out all the included salt. For some years I used to put the newly caught specimens of *Aurelia* into methylic alcohol, diluted with half its bulk of fresh water, and after leaving them in for some hours, with occasional movement so as to prevent adhesion to the glass, they were digested over and over again with fresh diluted alcohol. Specimens so prepared are so colourless and transparent that little of the general structure can be seen, but if kept many months in alcohol they turn somewhat brown-yellow and show their structure moderately well. On the whole it is, however, better to stain them. I have experimented with a great variety of colouring-matters, but find that the best are tincture of madder, Beale's carmine, methylene-blue, port wine, and tincture of galls. The canal-system and the general structure are well seen when Beale's carmine is used, but the colour is unnaturally bright, whereas the colour of madder is more in harmony with nature. Methylene-blue gives good results with fresh specimens, but does not stain those which have been kept long in alcohol.

Though I have many splendid specimens prepared as described, my last year's experience shows that, at all events for some Medusæ, a 4 per cent. solution of formic aldehyde is far better than alcohol. Into this the newly-caught animals were at once put, and it was subsequently used to dissolve out the salt. The superiority of this over alcohol is that Medusæ retain their form almost unaltered, and the most delicate parts can be moved about and arranged without fear of tearing. The only serious objection is that the very delicate fringe of *Aurelia* may be too rigid to be properly extended. No such objection exists in the case of *Cyanæa* or *Chrysaora*; and *Cyanæa* may be stained so as to be of nearly the natural colour, which is otherwise lost. In Fig. 3, I give an illustration of an *Aurelia* stained with carmine when in a 4 per cent. solution of formalin to which a little sulphurous acid was added.

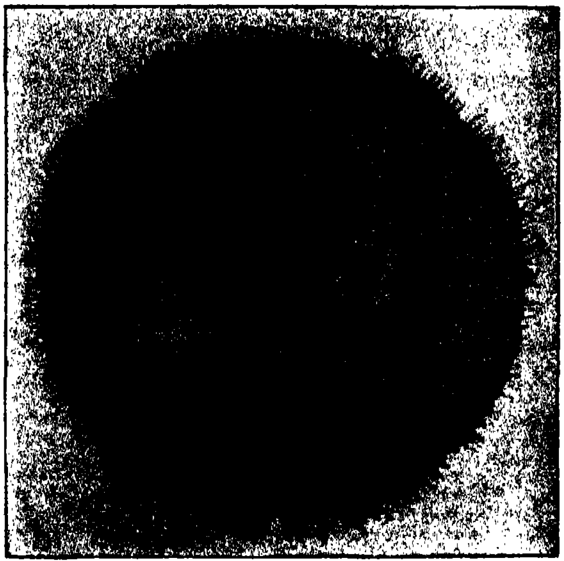

FIG. 3.—*Aurelia* stained with carmine.

In mounting Medusæ some special methods are necessary. Having removed the salt and stained the specimen as thought desirable, the lantern-slide glass is put into one of the usual developing dishes, and the animal floated out, and to some extent properly arranged, when under the liquid. The specimen may then be half an inch thick in the centre. No attempt should be made to dry it at once, since the greater part of the included liquid usually diffuses out, and nearly the whole can be drained off by keeping the slide inclined and covered up so as not to dry. In some cases the liquid passes off badly, but comes off rapidly, if a solution of gum is spread over the animal. As the edge dries, it should be covered with a strong clear solution of gum to which a little glycerine has been added to make it less brittle when dry, and this process continued until the whole specimen has been covered with gum. It should then be kept for some days in a wet state, so that the gum may soak well in, and any small bubbles not easily removed mechanically may disappear by absorption. At first I used to keep the specimens in a developing dish over a little water, covered up with a closely-fitting plate of glass, but sometimes in the course of a single day they became coated with a long growth of mould.

If, however, instead of water they are kept over alcohol diluted with an equal volume of water, they may remain wet for weeks, without any such growth of mould or such alteration in the gum as is produced by the action of stronger alcohol. It is very desirable not to finally dry too quickly, but, as it were, to anneal the specimens; since contraction may give rise to sufficient tension to cause them to crack and scale off from the glass.

I must now consider cases in which it is desirable to get rid of part of the colouring-matter, either natural or developed on keeping. Diluted sulphurous acid is very useful for this purpose, and remarkable results can be obtained with small fishes. If plaice about 2¼ inches long are kept in alcohol and then for a few weeks in diluted sulphurous acid, the earthy matter of the bones is dissolved out and only cartilage left; the general colour is reduced, and the thickness diminished; but strange to say, the arteries and enclosed blood are so little altered that when the specimens are mounted the aorta and branching arteries are well seen over the whole animal, as shown in Fig. 4, which, however, fails to show the more minute arteries, quite visible in the original.

Having duly prepared the dried animals, it may not be convenient to mount them at once in Canada balsam, especially when living on a yacht. They may then be kept in tin boxes with flannel which has been well dried at a fire, so as to absorb any moisture that may be in the air. When thus kept, even for many months, they usually do not undergo any sensible changes and do not go mouldy.

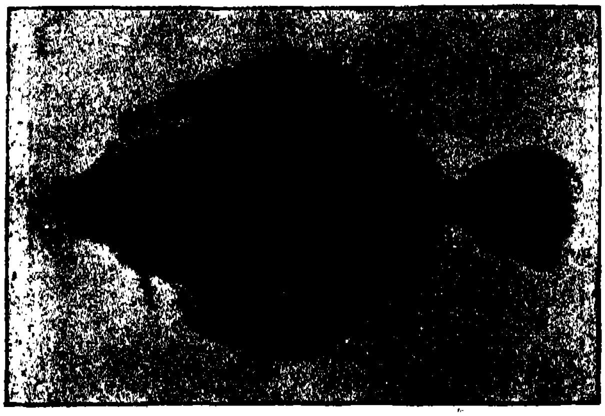

Fig. 4.—Plaice treated with sulphurous acid.

I must now conclude by describing the methods employed when finally mounting the specimens in Canada balsam. At the four corners of the glass should be gummed small pieces of blackened cardboard, of such a thickness that the cover-glass will just clear the object and not rock. The glass with the animal should be kept for a short or longer time in benzole; and, in the meanwhile, the cover-glass should be warmed on a suitable stand over a small burner, and a fair quantity of liquid balsam placed in the centre. The glass with the animal is then taken out of the benzole, and carefully placed over the balsam, so as to catch up as few bubbles as possible, the benzole causing the greater part to burst and disappear. If too little balsam has been used, more is easily run in between the glasses; and if only a few bubbles have been caught up, they soon disappear. If there are more than desirable, they can be got rid of by keeping the slide slightly inclined until they rise to one edge and can be removed. After keeping cold for a few days, for the balsam to harden the edges, it should be bound round with thin paper of the best quality, made thoroughly wet with gum. When this dries, contraction may squeeze out some superfluous balsam. This paper should then be varnished, and finally strips of good black paper should be *glued* well round the whole. All possible care should be used to enclose the balsam thoroughly, so as to avoid its turning yellow, and to prevent leakage, when the slide becomes warm in the lantern.

I have, however, had scarcely any trouble from this cause, since I have so completely fastened it in that the glasses or binding yield sufficiently. I may also say that though many of my slides have now been made for more than seven years, I have not observed any deterioration, but, on the contrary, many have greatly improved owing to the balsam having more completely penetrated into the tissues, and the included air disappeared. When this has taken place, the specimens are far more transparent and show their structure far better than the living or dead animals. Nearly all my slides have been kept in the dark, but some have been kept about the same time in a strong light at the Sheffield Public Museum, Weston Park, and, as far as can be judged, have not faded, even when imperfectly mounted.

H. C. Sorby.

OUR MINERAL WEALTH.

It would be difficult to conceive of a more concise and clearly expounded compilation of statistics and general information regarding mines and mining than that presented in the Third Annual Report upon the Mineral Industry of the United Kingdom of Great Britain and Ireland, which has been issued by the Home Office in the form of a Blue Book for the year 1896. The volume before us is a synoptical review of the condition of our own mineral industry, as well as that of other countries, which reflects unbounded credit upon its author, Dr. Le Neve Foster, and those who have assisted him in the work. It is divided into six parts, under the respective titles of persons employed, output, accidents, prosecutions, general remarks, and mineral statistics of the Colonies and foreign countries. It contains, in addition, nineteen appendices, and concludes with an exhaustive index.

The statistics for the United Kingdom distinguish between mines or underground workings and quarries or open workings; and the same figures are marshalled again and again under different aspects, so as to show their varying significance when coalfield is compared with coalfield, inspection district with inspection district, and county with county.

The first four parts include sixty-nine tables, in which the various classes of information susceptible of being so dealt with are compared with each other and with the corresponding figures for the year 1895. These are followed by six diagrams, on which are shown by means of curves, extending from 1851 to 1896 inclusive, the yearly variations in the numbers of persons employed above and below ground; the output and export of coal; output, export, and import of iron ore; deaths due to accidents generally; deaths from accidents, arranged in five distinct classes (explosions, falls of ground, in shafts, miscellaneous, and on surface); and the average quinquennial death-rate per 1000 persons employed, classified in the same way as in the last case. In Part iii. short descriptions are given of the circumstances under which the most important accidents of the year occurred; and throughout the volume many pertinent remarks are made, which serve to throw light upon the construction and meaning of the tables, point to the conclusions which they justify, and infer the lessons that are to be learnt from their perusal.

Turning now to a consideration of the subject-matter, we find that, taken altogether, there were 725,803 persons employed in or about mines during the year under review—576,325 working in the mines, and 194,478, including 5114 females, working on the surface. Of these numbers 678,690 were employed at 3260 coal mines, 16,819 at 136 iron mines, and 30,294 at 720 other mines. In addition to this there were 112,829 persons employed at 7758 quarries.

The quantity and value of the principal classes of minerals mined and quarried were as follows:—

Name of mineral.	Quantity.	Value at the mines or quarries.
	Tons.	£
Clays	11,341,782	1,442,069
Coal	195,361,260	57,190,147
Iron ore	13,700,764	3,150,424
Limestone ...	11,011,350	1,215,604
Sandstone ...	4,507,745	1,417,985
Slates and slabs ...	586,933	1,338,256

The total value of all the minerals worked in the kingdom was 69,088,366*l*., from which it will be seen that the value of the coal alone was practically five-sixths of the whole amount.

The number of separate accidents in mines was 886, involving the loss of 1065 lives, of which 147 were the victims of four explosions of fire-damp or coal-dust. The number of separate accidents in quarries was 117, in which 124 lives were lost.

A comparative table showing the death-rates from mining and quarrying accidents in different countries per 1000 persons employed, brings out some remarkable facts. Taking the column which represents the total for underground and surface for the year 1896, or in the absence of the figures for 1896 those of 1895, we find the following rates for the coal mines in some of the principal coal-producing countries of the world :—

Belgium	1·14
France (1895)	1·19
German Empire	2·57
Russia (1894)	1·29
United Kingdom	1·48
United States (1895) :—	
Colorado	3·75
Illinois	1·94
Indiana	2·70
Indian Territory	1·64
Kentucky	1·02
Missouri	2·07
New Mexico	16·88
Ohio	2·11
Pennsylvania :—	
Anthracite	2·924
Bituminous	1·825
Utah	1·50

According to M. Louis Lacombe, who compared the death-rates from accidents in mines in quinquennial periods, the last of which was 1890 to 1895, the ratios are as follows :—

Russia 2·90, *Belgium* 2·38, *England* 2·18, *France* 1·37.

The death-rate from accidents to railway servants in the United Kingdom for the year 1896 is given as 1·01 per 1000. The category includes such classes as carmen 0·47, clerks 0·17, mechanics 0·33, and signalmen 0·55, whose occupations are not by any means dangerous. On the other hand, the death-rate amongst those who have to do with coupling and uncoupling and making up the trains is infinitely more serious, such as shunters 4·94, yardsmen, 3·27, guards and brakesmen of goods trains 3·03. The highest of these figures pales before those applicable to sailing ships, amongst which we find :—

British sailing ships (1896)	12·9
German ,, ,, (1893)	15·8

These figures prove conclusively that the miner's calling, when brought into comparison with some other kinds of employment, is not of such a dangerous nature as is generally supposed. As having a bearing upon this question, however, it may be stated that one of the most gratifying features of the report is the curve given on Plate 4, which shows the death-rate per 1000 persons employed underground in coal-mines to have been reduced from the appalling figure of 5·5 in 1851 to 1·62 in 1896. This result—upon the attainment of which the Home Office, the Inspectors of Mines, and the mining community generally may well be congratulated—is undoubtedly due to the efforts that have been made by means of legislation and inspection to remove the causes which formerly led to such a lamentable loss of life. The loss of 147 lives in four great explosions in the year 1896 is a black spot in the record which ought never to have been there. I am glad to observe that the year 1897 has been entirely free from anything of the same kind, and I feel confident that if the new regulations regarding the watering of dusty places, and the use of explosives are attended to, or enforced with unflinching severity, we shall have seen the very last of such affronts to humanity and common sense.

The fines imposed upon owners and managers of mines for contraventions of the Mines Acts amounted to the insignificant sum of 258*l*. 13*s*. 9*d*., while the workmen for similar offences paid 459*l*. 6*s*. 8*d*.

The outputs of coal from a few of the principal coal-producing countries were as follows :—

		Metric tons.
1895	Austria, brown coal	18,389,147
	,, coal	9,722,679
1896	Belgium	21,252,370
1895	France, brown coal	437,000
	,, coal	26,109,893
1896	German Empire, brown coal	26,797,880
	,, ,, coal	85,639,861
1896	Great Britain	198,496,339
1895	Russia, anthracite	709,718
	,, coal	8,369,420
1895	United States, anthracite	52,616,149
	,, ,, coal	122,577,246

From these figures, with which I propose to bring this short and necessarily fragmentary notice to a close, it will be seen that this country still heads the list ; but the United States are quickly overtaking us, and will, no doubt, come into the first position in the course of the next few years.

W. GALLOWAY.

CALCIUM CARBIDE AND ACETYLENE.

AT the meeting of Institution of Civil Engineers on March 15, a paper on "Calcium Carbide and Acetylene" was read by Mr. Henry Fowler, and is here abstracted.

Acetylene was first isolated by E. Davy in 1837 from potassium carbide, a by-product of Sir H. Davy's method of manufacturing potassium. In the middle of the century Berthelot investigated its properties, and Wöhler produced it from calcium carbide. During the past few years it has assumed commercial importance owing to the development of the electric furnace, in which calcium carbide can be readily produced from lime and carbon. The furnaces used consist essentially of crucibles with carbon rods forming the positive electrode and a bottom plate lined with carbon for the negative. In the more recent furnaces these crucibles are mounted on small trollies so that they may be run out of the furnace when ready and a fresh one inserted without loss of time. The carbide formed is a hard, dense substance of reddish colour, unacted upon by most of the ordinary reagents. It is, however, rapidly decomposed by water into acetylene and lime, giving 5·9 cubic feet of acetylene, at a temperature of 60° F. and a pressure of 30 inches of mercury, per 1 lb. of carbide. As the power required theoretically to produce 1 lb. of calcium carbide in an electric furnace is more than 2 H.P. hours, its manufacture is at present restricted to localities where power is cheap, as for instance where water-power is available.

Acetylene is a colourless gas with an intensely penetrating odour, and is slightly soluble in water, and extremely so in some other fluids. It is endothermic, giving 407 calories per cubic foot, whereas theoretically its value is 336·5 calories. As an illuminant it gives the most brilliant light of all gases, 5 cubic feet per hour under suitable conditions giving 240 candle-power. For small consumptions, however, this value is not obtained, and ordinary burners after a short time became clogged with soot. The latter defect can be overcome by the use of an injector burner, which, however, requires a higher pressure. Various diluents have been suggested, but have not been tried on a practical scale. The flame has a high actinic value, and causes light colours to appear lighter, and dark colours darker than when exposed to sunlight. The gas, when inhaled, combines with the hæmoglobin and renders the blood incapable of taking up oxygen, and thus causing suffocation. It has, however, been shown that it is no more dangerous in this respect than coal gas.

Acetylene unites with copper, in the presence of moisture and ammonia, forming copper acetylide, and this when in a dry state is violently explosive. Silver is similarly acted upon.

Owing to the difficulty of obtaining the materials used in producing calcium carbide in a pure state, phosphoretted and sulphuretted hydrogen and ammonia are often found in the gas, and these should be removed by passing the gas through water and an acidified solution of a metallic salt. Nearly all proportions of air and acetylene are explosive, the gas itself being decomposed at 780° C. At higher pressures than 2 atmospheres, if this temperature is attained by a part of the gas, it is communicated throughout the whole mass and a violent explosion occurs, which causes the pressure to rise to eleven times the initial pressure ; but owing to cooling by radiation, &c., this is not reached in practice. Acetylene can be readily liquefied, having a critical temperature of 37° C. and pressure of 68 atmospheres. The resulting liquid is very light and has a high coefficient of expansion. Although this is a convenient method of storing a large quantity of gas in small bulk, it is unsafe, because of the ease and violence with which it explodes. The gas is extremely soluble in acetone; it has been suggested that this property might be used for its storage, but it has been shown that acetylene does not, even when thus dissolved, lose all its explosive properties.

Numberless devices for generating acetylene have been invented; its application, however, is more dependent upon the cost than upon the apparatus used in the manufacture. With calcium carbide at 16*l.* per ton, it can compete with coal gas at 2*s.* 6*d.* per thousand cubic feet, when flat flames are used for the latter, and a light of not less than 30 candles is required. This renders the gas peculiarly suited for buildings in which coal gas is not obtainable. It has been used for lighting a station on the Great Southern and Western Railway of Ireland, and at the Salford Docks of the Manchester Ship Canal. In the latter case, special portable generators are used which can be carried to any part of the docks, and which may be placed on the quay side and the gas led away to lamps placed in the holds of vessels. Amongst many other uses suggested are the lighting of lighthouses, lightships, buoys, military signals, &c., as a standard of light, &c. The price prevents its use for gas-engine driving. This reason also prohibits its use as an enricher of coal gas, as with low percentages the increase is not above 1 candle-power for 1 per cent. of acetylene. With "blue" water-gas it is even less applicable, as more than 10 per cent is required before any illumination is obtained. Methane and nitrogen are claimed to carry the gas without affecting its illuminating power.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Mr. R. T. Glazebrook, F.R.S., has accepted the post of Principal of University College, Liverpool.

Dr. H. W. M. Tims has been appointed professor of zoology in Bedford College, in succession to Dr. Benham.

Mr. Amos R. Eno, the New York multi-millionaire, who died a few weeks ago, left 50,000 dollars to Amherst College.

Miss Catherine W. Bruce, of New York, will give to the Yerkes Observatory, Chicago University, a photographic telescope of 10 inches aperture and 60 inches focal length.

The bequest by Catherine M. Garcelon, of California, to Bowdoin College, Maine, amounting to several hundred thousand dollars, has been confirmed by the Supreme Court of the United States.

The proposal to establish a chair of Anthropology and Anatomy, and also a chair of Physiology, in the University of St. Andrews, has been sanctioned by the University Court, and a scheme will be prepared.

The proposal to create a special degree of Doctor of the University of Paris (as distinct from doctor of a particular faculty) has been approved by the Superior Council of Public Instruction, and will shortly be carried into effect.

Among the degrees conferred at the annual graduation ceremony of the University of St. Andrews on March 25, was the honorary degree of LL.D., upon Prof. G. B. Howes, F.R.S., and the degree of D.Sc. upon Mr. A. T. Masterman.

The recent decision of the Government, abolishing building grants from Imperial funds to schools and institutions under the Department of Science and Art, has created dissatisfaction. A joint deputation of the County Councils Association, the Association of Municipal Corporations, and the Association of Technical Institutions waited upon Sir John Gorst at the Privy Council last week to point out the inconvenience caused by the withdrawal of the grants without previous notice; and Sir John Gorst promised to bring the views of the deputation before the President of the Council.

SCIENTIFIC SERIALS.

The *Journal of Electricity*, published in San Francisco, contains accounts of several large schemes for the electrical transmission of power in California. In one of these the water furnishing the power required for lighting Blue Lakes City, and several neighbouring townships, is conducted from the Blue Lakes, situated near the summit of the Sierra Nevada Mountains; while another installation at Bakersfield derives its power from the Kern River canyon. The "Wild West" is certainly making great strides in the practical applications of electricity.

In the current number of the *Physical Review*, Miss Isabelle Stone writes on the electric resistance of thin films; Mr. Edward B. Rosa describes a new form of electric curve-tracer; and Mr. C. H. Wind propounds a new theory of magneto-optic phenomena, the paper being a translation of one published by the Amsterdam Academy of Science.—Prof. C. Barus describes a method of obtaining pores or capillary canals of specified diameter; and Mr. C. P. Matthews discusses the methods of measuring mean horizontal candle-power of glow lamps, considering more especially the plan of rapidly whirling the lamp.

The latest number of the *Mathematical Gazette*, published under the auspices of the Mathematical Association, contains papers by Mr. E. Budden, on the conic through any five points; by Prof. Lloyd Tanner, on a class of algebraic functions; and a notice, by Dr. F. S. Macaulay, of an article by Miss C. A. Scott on Cayley's theory of the absolute. The functions to which Prof. Tanner's paper refers are those which involve only the differences of their arguments, and to which the same *diaphoric* was given by Cayley; and the object of the note is to suggest that an elementary discussion of these functions would be a valuable addition to the usual school course in algebra.

Symons's Monthly Meteorological Magazine, March.—West of England snowstorm, February 21. The fall commenced, roughly speaking, about 5h. p.m., and lasted until noon on the 22nd. The heaviest storms occurred in Hants, Dorset, Devon and Somerset. The fall reached, or exceeded, 12 inches over the area contained between two lines, the northern one running about E.S.E. from Watchet, through Yeovil to Lymington, and the southern one from Portlock, through Tiverton to Bridport; say about sixty by twenty miles. The greatest depth, about 24 inches, occurred nearly centrally in this belt, between Milverton and Crewkerne.—Results of meteorological observations at Camden Square for forty years (for February). It is interesting to note the exceptional temperature and rainfall of last February in connection with the mean of 1858–97, at Camden Square (N.W. London): maximum temperature in 1898, 56°·2; minimum, 24°·3. Mean of all highest maxima of previous forty years, 55°·2; mean of all lowest minima, 24°·1. Rainfall in 1898, 1·08 inches; mean of forty years, 1·61 inches.

The *Journal de Physique* for March contains papers on the following subjects:—On the magnetic torsion of iron and steel, by M. G. Moreau, in which the following laws are established: (1) at a point of a twisted wire outside the magnetic field the magnetic torsion is proportional to the torsion of the wire, to the square of the intensity of the field if the latter is weak, and independent of the diameter of the wire; (2) for points situated on different sides of the field the magnetic torsion has equal and opposite values if the ends of the wire are symmetrically placed with regard to the field; (3) along the length of the wire the torsion increases in proportion to the distance from the nearest end; it attains a maximum at the edge of the field, and vanishes at points inside the latter. The field in question is supposed to be a uniform field bounded by two parallel planes, beyond which the magnetic force vanishes.—M. Marage contributes a paper on ear-trumpets studied by the use of Koenig's flames.—M. G. Weiss describes an ingenious method, due to Hermann, of expanding any periodic curve in Fourier's series up to the first forty terms. The curve being drawn, forty equidistant ordinates are taken and measured, and corresponding to each ordinate a series of products is obtained from a table prepared by Hermann; and these are entered in columns on *quadrillé* paper. Finally a series of perforated cards are placed on the table thus formed; and to read off any coefficient in the expansion it is only necessary to algebraically sum the numbers seen through the openings in the corresponding card.—M. G. Charpy discusses entectic alloys, his paper being illustrated by figures showing their microscopic structure.—M. Gerrit Bakker, writing on perfect gases, gives a simple mathematical proof of the theorem that of the three characteristic laws of such gases, Boyle's, Charles's, and Joule's; any one is deducible from the other two.

SOCIETIES AND ACADEMIES

LONDON.

Physical Society, March 25.—Mr. Shelford Bidwell, President, in the chair.—Mr. A. A. Campbell Swinton read a paper and showed experiments upon the circulation of gaseous matter in a Crookes' tube. The stream-lines within a Crookes' tube are investigated by observing the direction and speed of rotation of a mica radiometer-mill, mounted on a sliding-rod, so that it can be moved along a line at right angles to the line joining the electrodes. The axis of the mill is at right angles to both these lines. If the mill is adjusted to a position between the flat plate and the cup electrodes, with its axis just sufficiently low to prevent equal and opposite simultaneous actions on the top and bottom vanes, it rotates always in the direction indicating a stream from kathode to anode. The speed is greater when the flat plate is the kathode. If, however, the mill is now moved below this line, a point is reached at which rotation ceases, and below this neutral point the rotation is suddenly reversed. Reversal is only to be observed with high degrees of exhaustion; the rotation is never so rapid here as in the first position. The mill rotates, and the reversal may be observed, whether cup or plate is made kathode, and the direction of rotation below the neutral point is always opposite to that in the position above it. A small Wimshurst machine is as effective as an induction coil in producing these effects. The experiments are intended to establish the existence, at high degrees of exhaustion, of a true anode-stream, *i.e.* a stream that travels from anode to kathode just in the same manner as the kathode-stream flows from kathode to anode. This anode-stream is charged positively; it is exterior to the kathode-stream; its velocity is less than that of the kathode-stream, but its velocity increases as the vacuum is improved. It seems probable that, in high vacua, some portion of the positive electricity passing through the tube, is carried by the positively charged atoms or particles that constitute the anode-stream. At lower degrees of exhaustion, the discharge passes through the tube chiefly by interchange of charges from molecule to molecule—a Grothüs chain. At very high vacua, however, when the mean free path is considerable, there may be to some extent a regular and complete circulation of positive and negative atoms, some of which pass from anode to kathode, and *vice versâ*, and deliver up their charges, not by interchange, but by direct convection, to the electrodes of opposite sign. Prof. Boys said he did not feel altogether convinced by the experiments, that the rotation of the mill was due to simple mechanical motion of the particles of matter between the electrodes. The weight of air left in the tube at such high degrees of exhaustion was extremely small; it was difficult to realise that its impact could produce the sudden mechanical effect observed at the moment of the reversal of the rotation of the mill. Mr. Wimshurst thought it important to keep in mind the existence of mercury-vapour in the tube. He also referred to some experiments in which a bar of metal was used to explore a focus-tube, by observation of the changes of luminosity produced in different positions. Dr. Chree said that if the rotations of the mill could be shown to indicate a velocity of the particles, of the same order as that observed in Crookes' experiments, it was safe to assume the existence of a similar cause. This might be important in deciding as to the general truth of the bombardment theory of Crookes. He asked whether the rotation had been investigated within the dark space around the kathode. Mr. Appleyard suggested that in tracing the cause of the rotation it would lead to simpler results if the vanes of the mill were made of some light conducting substance. Mica introduced difficulties owing to its retention of the charges. Prof. Boys pointed out that this could be done by gilding the mica. Mr. Campbell Swinton, in reply, said that the objection raised by Prof. Boys to the mechanical theory of the rotation would apply equally to the whole theory of electro-radiometry, including the case of the mill used originally by Crookes in the direct path of the kathode-stream. But it must be remembered that although the mass of matter present within the tube was very small, its velocity was proportionately great, it was of the order of 9000 kilometres per second; hence the contained matter might be conceived as capable of producing the observed acceleration, and Crookes' bombardment theory might with safety be adopted as a good working hypothesis. In the tubes used for these experiments, the exhaustion was carried so high that the negative dark space appeared to fill the whole tube. He had, so far, only tried mica for the vanes, but he thought it would be important to observe the result with a substance that did not retain the charges.—Mr. A. Stansfield then read a paper on thermo-electric pyrometers. In obtaining photographic records of the readings of thermo-electric pyrometers, the range of measurement is limited by the size of the photographic plate. For long ranges of temperature, the sensitiveness of the galvanometer must therefore be small. When it is desired to examine the temperature changes in detail—as, for instance, at the melting-points and freezing-points of metals—it is necessary to employ some device for giving a more open scale for the short temperature ranges that include those particular points. For this purpose two galvanometers are arranged in parallel, and so that they have their deflections recorded on the same photographic plate. The less sensitive galvanometer covers the entire range of temperature throughout an observation; the other is brought into use for magnifying special portions of the range. In this latter case, part of the electromotive force of the thermo-couple is compensated by an opposing electromotive force, applied at two points of the circuit, from a battery of Clark cells in series with a high resistance. The recording apparatus consists of a photographic plate mounted on a float that rises steadily when water is admitted into a cylinder. The source of light is a glow-lamp, enclosed in a wooden box. A brass tube, with a rectangular diaphragm at the end nearest the lamp, cuts off all light except that from a selected piece of vertical filament. Light from this filament is reflected by the plane galvanometer-mirror, and is focussed upon the photographic plate by a lens in front of the galvanometer; this method was suggested by Prof. Boys. The "cold" junctions of the thermo-couple are both inserted into a hypsometer. Very serious discrepancies exist between the indications of couples having nominally the same composition; they are too great to be attributed to accidental differences in the constitution of the alloys. Although with platinum alloys, coupled with platinum, 10 per cent. of iridium gives a more powerful couple than 10 per cent. of pure rhodium, the partial substitution of iridium for rhodium very considerably lowers its thermo-electric power. This result suggests that the change in the thermo-electric power of a metal depends upon the extent to which it is saturated with the alloying metal; thus 10 per cent. either of rhodium or iridium would, *per se*, more completely saturate the platinum than would 10 per cent. of a mixture of the two metals. The author discusses a series of curves derived from his experiments. He concludes that, thermo-electrically, there may be two classes of metals: (1) the ordinary metals, for which the curve representing the first differential of electromotive force with respect to temperature is a straight line, and (2) the platinum metals, together with a few, such as nickel and cobalt, for which the curve of this differential multiplied by the absolute temperature is a straight line. Dr. Chree discussed the curves, and asked how far stirring affected the results; he was inclined to think that stirring was a mistake. Mr. A. Campbell inquired whether the galvanometer kept its zero sufficiently well throughout the tests. Mr. Stansfield, in reply, said he had also come to the conclusion that stirring was a mistake; and it was a mistake to use a large quantity of metal. The pyrometers were sensitive to about a tenth of a Centigrade degree. He had experienced great difficulty with the zero of the galvanometer.—The President proposed votes of thanks to the authors, and the meeting adjourned until April 22.

Chemical Society, March 17.—Prof. Dewar, President, in the chair.—The following papers were read:—The reduction of bromic acid and the law of mass action, by Miss W. Judson and J. W. Walker. The reduction of bromic acid by hydrobromic acid constitutes a bimolecular reaction in presence of much sulphuric acid, and a tetramolecular reaction in absence of sulphuric acid.—The action of ferric chloride on the ethereal salts of ketone acids, by R. S. Morrell and J. M. Crofts. In dry ethereal solution, ferric chloride acts on ethylic ketophenylparaconate with production of a substance, $FeCl_2C_{13}H_{11}O_5$, which is decomposed by water yielding the basic ferric salt of ethylic phenylparaconate, $Fe(OH)(C_{13}H_{11}O_5)_2$; analogous results are obtained with the ethylic salt of the lactone of oxalcitric acid.—Note on the volatility of sulphur, by T. C. Porter. Sulphur sublimes rapidly at 100° in a vacuum.—Cannabinol, by T. B. Wood, W. T. N. Spivey and T. H. Easterfield. Cannabinol, the toxic resinous constituent of Indian hemp, boils at 400°, and its vapour density points to the molecular composition $C_{18}H_{24}O_2$;

it contains one hydroxyl-group, and is converted by prolonged boiling into a hydrocarbon of the composition $C_{10}H_{16}$.—Contributions to the chemistry of thorium, by B. Brauner. The author has investigated the properties of a new salt, ammonium thoroxalate, $Th(C_2O_4)_2, 2(NH_4)_2C_2O_4, 7H_2O$, and has obtained a simple method of purifying thorium compounds by aid of this salt; it is shown that the tendency to form complex oxalates amongst the rare earths is inversely proportional to the basicity of the earth.—On the atomic weight of thorium, by B. Brauner. From experiments made on ammonium thoroxalate, the author deduces the atomic weight of thorium as Th = 232·44, a result agreeing with the number obtained by Krüss and Nilson.—On the compound nature of cerium, by B. Brauner. From experiments on fractional crystallisation, the author concludes that cerium is associated with an element which possibly has the atomic weight of 110; another earth of lower atomic weight is perhaps present.—On praseodidymium and neodidymium, by B. Brauner. The author contributes a quantity of experimental data concerning praseodidymium and neodidymium, and considers that the eighth series of the periodic system may assume the form

Cs	Ba	La	Ce	Pr	Nd
133	137·4	138·2	139·7	141	143·6.

—Action of ammonia and substituted ammonias on acetylurethane, by G. Young and E. Clark. Ammonia and substituted ammonias react with acetylurethane principally in accordance with the equation

$$MeCO.NH.CO_2Et + NH_2R = MeCO.NH.CONHR + EtOH,$$

but secondary reactions occur under certain conditions.—Formation of oxytriazoles from semicarbazides, by G. Young and B. M. Stockwell. This paper describes the formation of oxytriazoles according to the equation

$$NHR.NH.CO.NH_2 + PhCHO + O = RPh.C_2N_3OH + 2H_2O,$$

in which R is an aromatic radicle.—Formation of *αα'*-dihydroxypyridine, by S. Ruhemann. *αα'*-Dihydroxypyridine hydrochloride is formed on boiling ethylic *αα'*-dihydroxydinicotinate with concentrated hydrochloric acid.—Position-isomerism and optical activity; the comparative rotatory powers of diethylic monobenzoyl and monotoluyl tartrates, by P. Frankland and J. McCrae.—The action of di-isocyanates upon amido-compounds, by H. L. Snape.—The action of alkyl iodides on silver malate and on silver lactate, by T. Purdie and G. D. Lander. The abnormally high optical activity of the ethereal malates and lactates prepared by the silver salt method is due to the simultaneous production of ethereal salts of alkyloxysuccinic and alkyloxypropionic acids respectively.—On the optical rotations of methyl and ethyl tartrates, by J. W. Rodger and J. S. S. Brame.

Anthropological Institute, March 8.—Mr. F. W. Rudler, President, in the chair.—The Hon. David W. Carnegie exhibited and described a large collection of objects of ethnological interest, which he had recently brought from Western Australia. He gave a description of the natives met with in his remarkable journey across the great sandy desert of the interior, between Coolgardie and Kimberley. Some of the men, notwithstanding the miserable character of their surroundings, were upwards of six feet in stature.—Mr. Robert Etheridge, curator of the Australian Museum at Sydney, sent for exhibition a large series of photographs of dilly baskets from North Australia. Many of these objects were highly ornate, and offered curious illustrations of aboriginal decorative art.—A paper on the folk-lore of the native Australians, by Mr. W. Dunlop, was read by Mr. T. V. Holmes. Most of the legends cited were taken down from the lips of the natives nearly half a century ago.

Entomological Society, March 16.—Mr. R. McLachlan, F.R.S., Vice-President and Treasurer, in the chair.—Mr. Champion exhibited specimens of *Acanthia inodora*, A. Dugès, from Guanajuato, Mexico. This insect, a congener with the common bed-bug, was found in fowl-houses, where it attacked poultry.—Mr. Wainwright exhibited a locust found alive in broccoli at Birmingham. The insect was identified by Mr. Burr as *Acridium ægyptium*.—Mr. Tutt showed a series of captured examples of *Calligenia miniata*, varying in colour and the amount of black markings, one example being a clear yellow and another orange.—The Secretary exhibited part of a series of holograph letters, &c., which he had discovered among old papers in the Society's library, including communications from Kirby, Spence, Darwin, Hope, Yarrell, and many other entomologists.—A paper by Mr. E. E. Green, of Punduluoya, Ceylon, entitled "Further notes on *Dyscritina*, Westwood," was read, and illustrated by specimens and drawings.—The author discovered two distinct species of *Dyscritina*, which he was able to keep in captivity, and rear from the early larval stage to that of the imago.—Dr. Chapman read a paper entitled "Some remarks on *Heterogyna penella*," giving a full account of its life-history.

Manchester.

Literary and Philosophical Society, March 22.—Mr. J. Cosmo Melvill, President, in the chair.—The President read a description and exhibited two specimens of *Strombus* (*Conomurex*) *belutschiensis*, just discovered by Mr. F. W. Townsend off the Mekran coast of Beluchistan, having been dredged at seven fathoms on a sandy and muddy bottom. This is a remarkable find, as it is nearly fifty years since any new species of this genus has come to light. It is most akin to *S. mauritianus*, Lam., but differs in several marked particulars.—Prof. Hickson communicated a paper by Miss E. M. Pratt, entitled "Contributions to our knowledge of the Marine Fauna of the Falkland Islands." The Manchester Museum received last summer a number of marine animals collected on the shores of one of the Falkland Islands by Miss Blake. As they were nearly all in an excellent state of preservation, the author was able to identify them, and to compare this common shore fauna, as a whole, with that of other temperate regions in the northern and southern hemispheres. The bearing of the facts of the geographical distribution of the species identified by Miss Pratt, upon Murray's theory of the bipolar distribution of marine organisms, was also indicated.

Dublin.

Royal Dublin Society, February 16.—Sir Howard Grubb, F.R.S., in the chair.—Prof. J. Emerson Reynolds, F.R.S., and Mr. Emil A. Werner made a communication on Goodwin's system of generating and using acetylene gas for illuminating purposes.—Prof. D. J. Cunningham, F.R.S., described the seventh cranial nerve in the orang, with illustrations by lantern projection.—Dr. W. E. Adeney and Mr. James Carson described the method they have followed in mounting the 21·5 feet concave Rowland diffraction grating, which has recently been acquired by the Royal University, Dublin.

Edinburgh.

Mathematical Society, March 11.—Dr. Morgan, Vice-President, in the chair.—The following papers were read: An analysis of all the inconclusive votes possible with fifteen electors and three candidates, and a suggestion for a shortened table of five-figure logarithms, by Prof. Steggall; note on the centre of gravity of a circular arc, by Mr. John Dougall; on the wave surface generalised for space of *n* dimensions, Prof. Schoute.

Paris.

Academy of Sciences, March 21.—M. Wolf in the chair.—Algebraic solutions of some questions concerning the indeterminate equations of the second degree of three terms, by M. de Jonquières.—Action of some reagents upon carbon monoxide, in view of its estimation in the air of towns, by M. Armand Gautier. A study of the various absorbents proposed for the estimation of carbonic oxide. Of these cuprous chloride and potassium permanganate react also with acetylene and ethylene; chromic acid is only partial in its action. A one per cent. solution of gold chloride gives an immediate precipitate with the pure gas, even in the cold, and forms a good qualitative test for CO mixed with air.—Observations of the sun, made at the Observatory of Lyons with the Brunner equatorial, during the fourth quarter of 1897, by M. J. Guillaume. Statistics referring to spots and faculæ are given.—New series of photographs of the complete chromosphere of the sun, by M. H. Deslandres.—On the singular transformations of Abelian functions, by M. G. Humbert.—On discontinuous functions capable of development in series of continuous functions, by M. R. Baire.—On the transformation of the X-rays by matter, by M. G. Sagnac. A metal upon which X-rays from a vacuum tube are falling emits secondary radiations differing in penetrative power from the original rays, and also differing according to the nature of the reflective substance. Thus aluminium gives off secondary rays which are much more penetrating than those of zinc.—Some applications of photographic irradiation, by M. Ch. Féry. On the hypothesis that the upper portion of the sensitive plate when illuminated by a ray acts as a true secondary source for neighbouring portions of the film, the conclusion is drawn that the apparent width of the line due to halation ought to grow in arithmetical progression when the quantities of light increase in geometrical progression, and this conclusion was verified completely by experiment.—Remarks on the preceding communication, by M. A. Cornu. This research throws light upon the divergences obtained in different observatories in the measurement of stellar magnitudes by photographic observations, although part of the observed variation is probably due to aberrations of the mirror.—On a universal magnifier for use in photographic enlargements, by M. J. Carpentier.—Determination of the density of gases with very small volumes, by M. Th. Schlœsing, junr. A detailed description of the apparatus used for the determination of gaseous densities by the hydrostatic method, together with the results obtained for air, nitrogen, carbon dioxide and sulphur dioxide. The results are accurate to one part in a thousand.—On neodymium, by M. O. Boudouard. Neodymium forms a double sulphate with potassium, which is more soluble than the corresponding salt of praseodymium, the difference in solubility being sufficiently great to allow of a fairly rapid separation.—On the explosion of mixtures of marsh gas and air by the electric spark, by MM. H. Couriot and J. Meunier. To avoid explosion, it is necessary to join up the two points between which the spark is produced by a secondary conductor.—On the properties of the phosphorescent sulphide of strontium, by M. José Rodriguez Mourelo.—On the oxidation of some amido- and thio-amido-compounds, by M. Œchsner de Coninck. A study of the oxidation of acetamide, thio-urea, phenyl-urea, phenyl-thiourea, sarcosine, and carbamic ether by alkaline hypochlorite solution.—On the chlorine derivatives of phenyl carbonate, by M. E. Barral. By the action of chlorine in presence of iodine upon phenyl carbonate dissolved in carbon tetrachloride, the di-chlor-derivative, $CO(O.C_6H_4.Cl)_2$, is obtained.—On the cholesterins of the lower plants, by M. E. Gérard.—Study of the anatomy and histology of the rectum and rectal glands of the Orthoptera, by M. L. Bordas.—On the reserve material in *Ficaria ranunculoides*, by M. Leclerc du Sablon. Estimations of the reducing and non-reducing sugars, dextrin and starch in the tubers of *Ficaria* were made monthly, and the results expressed in curves.—The tectonic of the secondary and mountainous region comprised between the valleys of the Ouzom and Aspe (Basse-Pyrénées), by M. J. Seunes.—On the phyllogenic classification of the Lamellibranchs, by M. H. Douvillé.—On the visibility of the X-rays to certain young blind persons, by M. Foveau de Courmelles. Only nine out of two hundred subjects examined were able to distinguish when the Crookes' tube was or was not excited. No sensation was perceived by those totally blind, only those blind by a peripheral lesion, or having a vague perception of light, being sensitive to the X-rays.—Applications of radiography to the study of digital malformations, by MM. Albert Londe and Henry Meige.—Application of radiography to the study of a case of myxœdema; development of the osseous system under the influence of the thyroid treatment, by MM. Georges Gasne and Albert Londe.—Experimental paralysis under the influences of venoms, by MM. Charrin and Claude.—On the eruptions of Vesuvius, by M. E. ST. LOUIS.

Academy of Science, February 21.—Dr. R. J. Terry exhibited a specimen of a cervical rib from a human subject, and discussed the occurrence of structural anomalies of this character.

March 7.—Prof. C. M. Woodward presented a paper embodying an analytical discussion of the efficiency of gearing under friction. Few works on applied mechanics, the speaker stated, give any discussion of the matter. Only spur wheels with epicycloidal and involute teeth were considered. For the sake of comparison, a table was produced giving the efficiency for different values of the coefficient of friction *f*, and for equal wheels and for the same number of teeth, 12, on each wheel.

Efficiency of Spur Wheels.

	Equal wheels with 12 teeth each.				
Kind ...	*f* 0·03	*f* 0·10	*f* 0·15	*f* 0·20	*f* 0·25
Epicycloidal	0·9915	0·9693	0·9514	0·9318	0·9103
Involute ...	0·9923	0·9746	0·9622	0·9501	0·9381

—Dr. Amand Ravold demonstrated the method, recently introduced by Hiss, of differentiating the typhoid bacillus from bacillus coli-communis, by the use of semi-solid acidulated media, in which, at blood temperature, the round colonies of the typhoid bacillus assume a peculiar fimbriated form of growth, because of the motility of the bacteria in the slightly yielding medium, which in most cases readily distinguishes them from the more whetstone-shaped colonies of the colon bacillus, which does not produce the peculiar fimbriation in plate cultures. In tube cultures in the same general medium, but prepared with a slighter acidity and somewhat less solidity, a uniform clouding of the entire tube, due to the swarming of the bacteria, was shown to be characteristic of the typhoid bacillus, while the colon bacillus was definitely confined to the immediate vicinity of the thrust. The media in both cases are made up without peptone. The formulæ are:—

For plate cultures.		For tube cultures.	
Agar	10 grams.	Agar	5 grams.
Gelatine	25 ,,	Gelatine	80 ,,
Beef extract ...	5 ,,	Beef extract ...	5 ,,
Glucose	10 ,,	Glucose	10 ,,
Salt	5 ,,	Salt	5 ,,
Normal acid ...	20 cc.	Normal acid ...	15 cc.
The whole increased to 1000 cc.		The whole increased to 1000 cc.	

The growth of the two species in question, on potato and in milk cultures with litmus, was also demonstrated.

AMSTERDAM.

Royal Academy of Sciences, February 26.—Prof. van de Sande Bakhuyzen in the chair.—Prof. Schoute, Necrology of Dr. F. J. van den Berg (1833-1892), Professor of Mathematics at the Polytechnic School of Delft (1864-1884).—Mr. Muller, correspondent of the Academy in the Dutch East Indies, made a communication on the triangulation of Sumatra. When, on the completion of the triangulation of the "Government of the West Coast of Sumatra," the triangulation of South Sumatra was to be commenced, the intention was to start from the triangulation points, determined in 1868 and 1869 in the Lampong districts by the staff of the then Geographical Service. On inquiry being made towards the end of 1895 into the condition of the pillars erected on those points, they were all found to have disappeared, so that the staff of the Triangulation Brigade of the Topographical Service, appointed to carry out the triangulation of Sumatra, had to effect a new connection across the Strait of Sunda. The Langeiland-G. Radja Bara side of the Sumatra chain was therefore connected by means of three triangles with two sides of the Java chain, viz G. Karang-Batoo Hideung and G. Karang-G. Gede; by means of four triangles the same side was now connected with the point G. Dempoo in the Lampong districts, which had been selected for astronomical station for the orientation of the Sumatra triangulation. In 1896 the building of pillars was commenced, and in the course of 1897 the angular measurements at the nine stations, besides the determination of the latitude and azimuth at G. Dempoo were completed. The mean error of the result of the determination of the latitude of G. Dempoo is 0"·21, and that of the result of the determination of the azimuth 0"·27. The latitude of the point G. Karang, as calculated from the Sumatra chain, differs 6"·5 from that derived from the Java chain, which difference may partly be ascribed to local declination. The azimuths at that point differ 5"·3, which is probably to a great extent due to the accumulation of errors in connection with the great distance of the point Genook in Japara, which served as starting-point for the computations of latitude and azimuth in the Java chain of triangles, and which is 540 km. from Karang. The publication of the determinations of latitude and azimuth carried out by the Geographical Service in West Java, will probably throw more light on the cause of these differences.—Prof. Kamerlingh Onnes communicated on behalf of Mr. N. Kasterin, of Moscow, experiments on, and a theory of, the propagation of sound through a non-homogeneous medium. The solution given has been rendered general by means of spherical functions for a medium consisting of equal spheres in a state of rest and arranged parallelopipedically. Applications were made to the case when the dimensions of the spheres are small in comparison with the wave-length. Perfect analogy with the dispersion and absorption of light was found; the index of refraction, the dispersion curve, the absorption coefficient and the absorption bands in the acoustic spectrum were determined. The experiments were made with balls, arranged in tubes of quadratic cross section. Complete correspondence between observation and theory was found. The solution was also found for a medium, composed of gaseous spheres. Experiments, relative to this case, were made by placing a series of resonators in a Kundt's tube. Phase retardation on waves passing through impediments was previously observed by Kasterin in the case of capillary waves.—Prof. W. H. Julius presented a paper on a simple extension of the Gauss-Poggendorffian method of reflector reading, by which it becomes possible directly to read not only *tg* 2*a*, but also *tg* 4*a*, *tg* 6*a*, *tg* 8*a*, *tg* *a* . . . *ad lib.* This effect is produced by repeated reflections of the incident rays between the reflector and the slightly silvered back of a small glass plate, placed in front of it. A photograph of the field of vision in the telescope was added, in which the four images of the scale are seen simultaneously, the readings of which yield the various multiples of 2*a*.

THURSDAY, APRIL 7, 1898.

A MALPIGHI BICENTENARY VOLUME.

Marcello Malpighi e l'opera sua. Scritti varii. Pp. 338. (Milan : Vallardi, 1897.)

THE great Malpighi—Marcello Malpighi—to give him his full name, anatomist, physiologist, botanist, pathologist, biologist, and above all natural philosopher, striking and powerful man of science in the latter half of the seventeenth century, was born on March 10, 1628, in the house of his father, a farmer in easy circumstances in the outskirts of the town of Crevalore, which lies in the neighbourhood of Bologna.

Last year the town of Crevalore, with the help of others, erected in its market-place, opposite the town hall, a bronze statue of their great townsman as a tangible token of how much they felt his worth. Dr. Pizzoli, the Secretary of the Committee for the erection of the monument, conceived the happy idea of combining with the memorial of bronze one of another kind—one which should not be stationary at Crevalore, but wander far and wide—a printed book in which several men of science of different lands and pursuing different paths of inquiry might state what they knew and thought of their great common master of old times. Circumstances prevented the two memorials being completed in 1894, which would have been the bicentenary of Malpighi's death, this taking place on November 29, 1694 ; but the statue was unveiled last November, and the memorial volume is now before the world.

It would be out of place in a notice such as this to dwell at length on Malpighi's place in the history of biological science, or to attempt to discuss the value of his many and varied labours. I must content myself with giving a brief account of the contents of this memorial volume.

The several contributions are very varied, both in length and character ; and as one reads them in succession, a great deal of repetition is met with ; but this is unavoidable in a work written in the way in which this is written ; and it may at least be said that all the contributions will reward perusal.

G. Atti (of Bologna) gives a biographical sketch, the shortness of which is, I cannot help thinking, much to be regretted ; and though Prof. Atti has written at length elsewhere, I feel sure that a fuller relation of Malpighi's life, some genial narration of his personal story, free from any critical account of his scientific labours, would have been a very acceptable addition to the volume.

Virchow contributes an éloge, Haeckel an appreciative estimate of Malpighi as a philosophic naturalist, De Michelis (of Ravenna) an essay on Malpighi's place in the History of Thought, Todaro (of Rome) a sympathetic view of him as a pioneer in biological studies and as an advocate of experimental medicine being considered as an integral part of the study of living things, and De Giovanni (of Padua) an exposition of his place in the development of pathological science. All these are short, while the contribution of Weiss (of Messina), entitled a general introduction, dealing as it does with the several aspects of Malpighi's scientific activity, is necessarily longer.

Kölliker supplies a very brief but pregnant and admirable statement of the many notable discoveries in general anatomy which we owe to Malpighi, Romiti (of Pisa) an estimate, also short, of Malpighi's place in the history of topographical human anatomy, while Eternod (of Geneva) dwells more in detail on his worth as being one of the earliest to grasp the value of that research into minute structure, whether of plants or animals, which we now call Histology, and indeed as being one of the founders of a branch of biological science which has, especially in these latter days, gathered in so many and such important truths. Cattaneo (of Genoa) expounds at length and in detail the great man's many and varied contributions to comparative anatomy ; and Perroncito (of Turin) adds a detailed account, which by reason of its very detail is most interesting, of Malpighi's famous work on the silk worm, "De Bombyce." It will be remembered that Malpighi was led to undertake this investigation in consequence of a letter which the Royal Society of London addressed to him, through the hand of its Secretary Oldenburgh, and that the volume containing the account of the investigation was published by and on the financial responsibility of the Royal Society, being the first of a series of works by Malpighi thus published. Indeed after this onward nearly all Malpighi's inquiries were published by the Royal Society.

We learn from Dr. Pizzoli's sympathetic preface that it had been intended to include a contribution on Malpighi as an embryologist, one of Malpighi's works being "De formatione pulli in ovo." Through misadventure this intention failed ; but the value of Malpighi's work in this direction is touched upon by more than one of the contributors just mentioned.

Two contributions deal with Malpighi's botanical researches. At its meeting of December 7, 1671, there was read before the Royal Society a preliminary sketch by Malpighi of his botanical investigations under the title of "Anatomes Plantarum Idea" ; and at the same meeting our countryman Nehemiah Grew laid before the Society a copy of his work entitled "The Anatomy of Plants begun," which the Society in the previous spring had ordered to be printed. Much controversy has arisen in respect to the relative merits of Malpighi and Grew as the founders of the anatomy of plants. One of the above two contributions is a short essay by Strasburger in which, while giving Grew all his due as an original inquirer, he claims for Malpighi a higher place as being a mind of wider grasp, as being one who in investigating plants was seeking a clue to the secrets not of plants only but of all living things. The other contribution, by Morini, is much longer and deals in detail with all Malpighi's botanical studies, incidentally touching also on the controversy about Grew, and giving a brief sketch of the condition of botany before Malpighi began his work.

I have myself contributed a condensed account of Malpighi's relations with the Royal Society, explaining in a simple manner how the correspondence between the one and the other began, how the Society undertook in succession the publication of Malpighi's most important works, and how cordial and close was the intercourse between the great Italian inquirer and the learned

English body. Some of the letters which passed between Malpighi and the Royal Society appear in the "Opera Omnia." But many others are preserved in the archives of the Society, and I thought that it would be well if all these saw the light. I accordingly have added these letters—some from Malpighi to the Society or to one or other of the Secretaries, others from the latter to Malpighi, in all forty-two in number—as an Appendix to what I have written. In doing this I received most valuable assistance from Mr. Herbert Rix, the late Assistant Secretary to the Society. Probably some printer's and other verbal errors have escaped the notice of both of us.

Lastly the volume contains an account, by L. Frati, of the various medals issued in honour of Malpighi, and a bibliography, by C. Frati, both of Malpighi's own writings and of various writings about him.

Dr. Pizzoli may certainly be congratulated on having produced an interesting and useful volume, the reading of which cannot but do good. To stand back from the present rush of inquiry and controversy, to look across two centuries at a great man, struggling with the beginnings of problems which have since come down to us, some in part solved, but others with their solutions put still further off by the very increase of knowledge, is a useful lesson to every one of us. In any case the great men who in the past opened up for us paths of inquiry—and among these Malpighi takes a foremost place—ought not to remain mere names, known to us chiefly through being attached to some structure or to some piece of apparatus. We ought all of us to be able to form some idea of what they were and what they thought. The present volume will be a great help to any one, who can read Italian, towards such an end in respect to Marcello Malpighi.

M. Foster.

THE ARYO-SEMITIC SCHOOL OF MYTHOLOGY.

Semitic Influence in Hellenic Mythology, with special reference to the recent mythological works of the Right Hon. Prof. F. Max Müller and Mr. Andrew Lang. By R. Brown, junior. Pp. xvi + 288. (London: Williams and Norgate, 1898.)

IT has been a well-known fact for many years past that the breach between the linguistic and anthropological schools of mythology was growing steadily, and it was evident that a serious rupture must eventually occur. It was felt that the venerable linguistic method was being slowly but surely undermined by many workers, and that the anthropologists were consolidating their position in a remarkable manner. The rupture, however, might have been delayed, and the two schools might have made concessions mutually in the interests of the peace and progress of the science, the advancement of which each party professed to have at heart, had they been allowed to do so. But it was not to be, and the immediate cause of battle between the rival schools was the publication of Prof. Max Müller's "Contributions to the Science of Mythology," wherein the great writer discussed with his characteristic learning the subjects on which he is the first authority at present. This work was violently attacked by Mr. Andrew Lang, who, it cannot be denied, impressed many by his skill in word trickery and brilliant phrases, and the unwary reader may quite well be forgiven if he was led astray by a flood of journalistic eloquence. Those, however, who had any knowledge of the subject saw at once that Mr. Lang did not represent the anthropological school, and that he had no right to pretend to do so; for as is well known he has shown no evidence that he possesses any special knowledge of any one of the subjects which go to form that complex whole called mythology. Prof. Max Müller may have made mistakes, but he knows his languages; Mr. Lang has a competent knowledge of no Oriental language, and can never now acquire even a working hold upon the dialects of the East, wherein Prof. Max Müller was an authority thirty years ago. To us it seems doubtful if Mr. Lang has sufficient knowledge of Eastern linguistics to understand all the points of Prof. Max Müller's position. In any case Mr. Lang's attack upon the Oxford Professor was futile, and all it served to do was to show that Mr. Lang had mistaken his own powers, and that he had without any proper authority assumed to himself the right to act as spokesman for the anthropological school of mythology. Now, it seems, another combatant has joined in the fray in the person of Mr. Robert Brown, junior, who, though wishing to support Prof. Max Müller against Mr. Lang, has a few objections to urge against the venerable scholar, and an axe of his own to grind. Mr. Brown, like Mr. Lang, makes himself the spokesman of a "School," which, he says, "for present purposes, I may style the Aryo-Semitic," and though he recognises "the vast results that have sprung from the scientific application of Aryan linguistics," he is "in entire sympathy with the researches of anthropology in general, and of folk-lore in particular." The cynical outsider will have some difficulty in understanding the position of such a Mr. Facing-both-ways. As far as we can see, Mr. Brown has printed his book to prove that Hellenic mythology owes a pretty big debt to Semitic peoples; but then, no one, so far as we know, ever doubted this obvious fact. Mr. Brown has also taken a great dislike to Mr. Lang, the evidence of which forces itself upon the reader in several places. Mr. Brown's dislike is so strong that in order to relieve his feelings, he is obliged to write a number of childish things, which any friend of his would have excised from his manuscript before it was printed. Mr. Brown also falls foul of Mr. Frazer, the author of the "Golden Bough," and when, like Mr. Silas Wegg, Mr. Brown is obliged to "drop into poetry," and to print in a book intended to be serious the silly lines (p. 14),

O Mr. Frazer, Mr. Frazer, what a man you are!
I never thought when you set out that you would "go so far,"

we can only regret that Prof. Max Müller has been "taken up" by Mr. Brown. Moreover, to talk of a "Covent-garden-market theory of mythology" (p. 15) is hardly the language which we should expect from one who calls himself a supporter, and, in some respects, a disciple of Prof. Max Müller.

It is time to ask now what Mr. Brown's qualifications are for his self-assumed *rôle* of defender of Prof. Max Müller. In reading over his pages we see that a great many languages are quoted, and that a vigorous attempt has been made by Mr. Brown to mark the quantities of the vowels which occur in the extracts; the pages look not only learned but terrible. But it is one thing to be able to find words in a dictionary, and another to know the language to which the dictionary is the key. Mr. Brown has written many papers on astronomical matters, and we are willing to assume, for the sake of argument, that they may be of value; but from the manner in which he writes the words of one of the languages which he quotes, that is to say Hebrew, we are convinced that his knowledge of it is of an elementary character. An example or two will show what we mean. On p. 115 he speaks of Sanchouniathan, meaning Sanchon-yathan (we leave out the vowel quantities because they are not necessary); this spelling shows that Mr. Brown took the name from a non-English book, and did not know that Sanchôn was the form of the god's name. The spelling Aschthârth (pp. 115 and 182) is another example of the same thing. On p. 116 (*bis*) he prints Qarnâîm for *Qarnayim*, which shows that he does not know how to transcribe the dual ending in Hebrew; the *a* cannot be long here unless it carries the accent. On p. 133 he gives *dayon* as the Hebrew for the word "judge"; as a matter of fact it is *dayyân;* on p. 149 he writes Ai lênu for *î lânu;* on p. 181, Qastu for *Qashtu;* on p. 182, Dagîm for *Dâgîm;* on p. 142, Kîyûn for *Kîyyûn;* on p. 133, anoshîm for *ănâshîm;* and so on in many places. These are not mere misprints, and they show the want of knowledge of elementary principles of Hebrew grammar. He often vocalises Phœnician words in defiance of all the laws which governed the Masoretes in their deliberations, and yet when he has good authority for adding the lengths of the vowels he fails to do so; see on p. 182, where he writes Kimah for *Kîmâh*. We cannot attempt to follow Mr. Brown in his Accadian, and "Hittite," and other little-known dialects, but the general impression which we gather from his book is that he is little more of a genuine expert in linguistic mythology than is Mr. Lang; and Mr. Lang is a brilliant, amusing writer, whilst Mr. Brown is not. The silly remarks on p. 85 are in very bad taste. The scholars of Oxford, Cambridge and London are only too glad to help on learning in any shape or form, and no honest worker is pushed aside at any of these places because he does not live there, or is not a graduate of the University. When professors of the Aryan and Semitic languages are convinced that Mr. Brown has a competent knowledge of these tongues, they will be prepared to believe that he knows accurately Accadian and "Hittite," and to accept his conclusions; meanwhile Mr. Brown's present work will delay that result.

DEVELOPMENTAL MECHANICS.

Programm und Forschungsmethoden der Entwicklungsmechanik der Organismen, leichverständlich dargestellt. Von Wilhelm Roux, o.ö. Professor der Anatomie und Direktor des anatomischen Instituts zu Halle. Zugleich eine Erwiderung auf O. Hertwig's Schrift Biologie und Mechanik. Pp. 203. (Leipzig: Verlag von Wilhelm Engelmann, 1897.)

IT is questionable whether Dr. Wilhelm Roux does not do more harm than good to the cause which he has at heart by his excessive fondness for programmes. The work which lies before us is at least the fourth of a series of expositions of the nature, aims and methods of the subject of developmental mechanics, and it differs but little from its predecessors (consisting as it largely does of extracts and quotations from them, with explanatory and justificatory additions) in the complacent, not to say assertive, manner in which its author extols his own methods and aims at the expense of those which have hitherto been in use among zoologists. To our thinking Dr. Roux's weakness lies not in his aims, which are legitimate and praiseworthy, nor in his methods, which are carefully considered, but in the persistence with which he lectures his colleagues on their shortcomings and on his own rectitude. Different persons are differently affected by oft-repeated homilies: some will acquiesce, the greater number will escape by indifference, and others will be goaded into active hostility to what they regard as the pretensions of the author. To the last category belongs Dr. Oscar Hertwig, who has recently attacked Roux in an unsparing manner, asserting that his programme is obscure and wanting in novelty; that since it is not new the very name of developmental mechanics is superfluous and, moreover, incorrect; that the method, in so far as it is new, cannot lead to any progress in biology; that it is inapplicable to the subject; and finally, that in so far as it has been applied by Roux, it has been applied in so faulty and slovenly a manner as to have produced error instead of enlightenment.

The issue between the new method and the old is very clearly raised, and the present work is chiefly concerned in repelling Hertwig's attack. It would take far too much space to attempt to describe the numerous questions which enter into the dispute, questions which involve discussions on the laws of causation, on the theory of mechanics, on nomenclature, and on numerous matters of fact.

Our general impression after reading Roux's article, is that he has come out of the contest with credit, and that in some particulars he has successfully overthrown Hertwig's attack. It must be remembered that Roux is by no means an empty theorist: he has preached, as we think, over-much, but he has also practised largely and with great success, and whatever *à priori* objections may be taken to the methods which he inculcates, he has been able to show us, by the results which he has himself achieved, that the method of experiment may be applied with great advantage to the elucidation of embryological phenomena. His contention in this and earlier essays is, that the biological methods lately in vogue are purely descriptive and based upon simple observation, and that therefore they do not, and cannot, give a causal account of biological phenomena. To obtain a knowledge of causal relations, one must, says Roux, have recourse to experiment, and further than this, to "causal analytical experiment."

It is not quite easy to understand the antithesis between simple experiment and causal analytical experiment, though our author evidently attaches special value to the latter term, for he repeats it again and again. Seemingly it means nothing more than that every experiment should be conducted with strict attention to the particular question to be solved and with due regard to secondary and disturbing influences, conditions which, to the ordinary uninstructed person, would seem to be necessary to every experiment worthy of the name. This however, is a matter of secondary importance; Roux insists specially on the use of experiment—accurate painstaking experiment—in biological investigation. He further indicates that developing organisms afford the most fruitful field for the experimental method, for there one may most certainly hope to discover the formative forces which by their interaction co-operate to produce those formal changes which we have come to know by the method of simple observation. It is on this subject that Hertwig differs most widely with him. According to the latter author, there is no place for the experimental method in embryology. Experiment is nothing more than the production of changes of state in existences. In the inorganic world we have to deal with relatively stable existences, and before we can make any assertions of cause and effect about them we must bring about a change of state in them. In the organic world, however, the case is widely different. It is the characteristic of living bodies that they are always undergoing changes of state, and the changes are most characteristic and most conspicuous during the period of embryonic development. Thus nature does for man in the organic what he himself has to effect in the inorganic world, and it is only necessary for him to observe and record the natural successive changes in order to be able to state a series of relations of antecedent and consequent. Thus Hertwig says—

> "Every antecedent state is the cause of that which follows it . . . a living frog's ovum is the antecedent which of invariable necessity leads to the establishment of a frog's gastrula as a consequent, if only the conditions and circumstances necessary to further development are fulfilled. For the words antecedent and consequent one may equally well substitute the words cause and effect. Hence embryological research, which 'describes' the change of the frog's ovum into the gastrula, asserts a causal relation, and in so far as it does this for all the stages of the development of the frog from the egg, it asserts the law of the development of the frog. In this sense the research of the last fifty years has brought to light the most important causal knowledge. Is not the recognition that the ovum and the spermatozoon are simple elementary organisms and that, as such, when the appropriate conditions are fulfilled, they unite in themselves all the causes (exception being made of *causæ externæ*) which are necessary to the production of a new being, and that they in fact bring it into existence, is not this a causal recognition?"

The above paragraph is quoted by Roux as illustrating very clearly the difference between his and Hertwig's standpoints. Hertwig imagines that the ends of science are fulfilled by the enumeration and description of different states, and holds that our task is finished when we are able to assert that any one state invariably proceeds from another state immediately preceding it. Roux admits the necessity and value of this knowledge, but declares that it is only a step towards a causal explanation of the phenomena, and is far from satisfying our desire for a full explanation.

An illustration will serve to make the point clear. Hertwig's position would be that of an astronomer who was content with the truth arrived at by Kepler, that the observed successive positions of the planets are due to their paths being elliptical. Having ascertained the nature of the planets' orbits, he would be justified in asserting that the observed positions of the planets were due to—that is, were caused by—the fact that their paths are elliptical. But this would not be a sufficient causal explanation of the planetary movements. There is clearly a further question as to why the paths are elliptical, and the elucidation of this question was reserved for Newton. Hertwig would suggest that embryological inquiry should stop short at a point analogous to that gained by Kepler, and that we should content ourselves with the assertion that the states which we observe in individual ontogenies are what they are because the organisms in question describe a sort of normal curve in the courses of their development. It is hardly possible to refuse one's sympathy to Roux when he declines to be content to stop at this point, and urges that the knowledge hitherto acquired is but a preliminary to further inquiry. Everybody who has studied and reflected upon the facts of embryology must have felt the necessity for further enlightenment as to why, and in virtue of what inherent energies the ovum is able to go through the complex succession of changes which lead to the establishment of the adult individual. Various theoretical solutions of the problem have been offered, but they have not proved satisfactory. Roux steps forward and shows that the only possible solution is by the method of experimental investigation. Since he himself admits that the problem was present to the mind of von Bär, it is clear that his aim is not new, and in this unimportant matter Hertwig is right; but if the aim is not new, it has only recently become practical, and Roux may lay claim to the chief credit of having seen that the time was ripe for trying to realise it.

But it is one thing to have a legitimate and definite object in view, another thing to devise the most appropriate means of attaining to it. Roux has entire faith in experiment. Hertwig objects to the experimental method, because in the act of making an experiment one disturbs the normal course of vital phenomena, and obtains abnormal results, from which nothing can with certainty be predicated as regards natural processes. Bütschli has in a similar sense objected that the introduction of disturbing factors into ontogeny involves a complication in the results, which can only be justly estimated when the elements of the mechanics of normal developmental processes are well ascertained. The answer to this is that no progress is possible if one allows one's self to be discouraged by *à priori* objections and difficulties, and that the method of experiment, so far as it has gone, has been successful almost beyond anticipation.

As regards the title "Developmental Mechanics" (*Entwicklungsmechanik*), which Roux justifies at some length, it need only be said here that the equivalent "Experimental Embryology" most generally used in England and America, though not expressly disavowed by him, differs in its connotation from the title which he has selected. Thus on p. 176, "Entwicklungsmechanik bedeutet also die Lehre von den Entwicklungsbewegungen": the essential idea is not contained in the term Experimental Embryology.

Roux's last task is to defend his practical methods and results against the criticisms of Hertwig, who has not hesitated to say that his preparations were so imperfect in point of histological technique that nothing could be inferred from them. Roux retorts with a criticism of Hertwig's control experiments on the same objects (frog's ova), and it is difficult to decide between two observers who mutually accuse each other of inaccuracy and want of attention to detail.

So far as one can judge the advantage in the polemic lies with Roux, the more so because he invites our confidence by asking any one who is interested to come and inspect his preparations of hemiembryos, and to judge for himself whether or not he has described them truly, and whether they do not support the theoretical conclusions drawn from them.

BRITISH VERTEBRATES.

A Sketch of the Natural History (Vertebrates) of the British Isles. By F. G. Aflalo. 12mo, pp. xiv + 498. Illustrated. (Edinburgh and London: Blackwood and Sons, 1898.)

WITH the host of books in existence on British animals, it is a somewhat curious fact that, so far as we are aware, there is none which treats of all the vertebrates collectively, with the exception of Jenyns's "Manual," published in 1835. Still more curiously, that particular work happens to be omitted from the very useful bibliography Mr. Aflalo gives at the end of his little volume! Under these circumstances, the work before us fills a distinct gap; and as it is beautifully illustrated and brightly written, it ought to command a ready sale among those desirous of knowing something about the higher animals of our islands without being bored by technicalities.

Needless to say, it is not a book for the professed naturalist, and should not therefore be criticised from his standpoint. It has no pretence to be an advanced educational text-book; but is intended to appeal to those who have the "field-fever" strongly developed, and who are certainly in need of a cheap and portable volume dealing with all the vertebrates to be met with by field and flood in the British Isles. To be as accurate as possible without being dry, to produce a chatty little handbook, and not a dissecting-room manual, seems to have been the main object of the author; and in this laudable endeavour, in our opinion, he may fairly claim to have succeeded.

One very notable feature in the book is that scientific names are relegated to a series of tables, prefixed to the groups to which they refer, and that in the text the animals appear under the popular designations alone. This certainly renders the volume much more readable than would otherwise be the case. Special attention is given to the life-history of each animal treated; but descriptive details sufficient to distinguish the species from its British relatives are added, and in those cases where we have perused them, appear all that can be reasonably required.

Any nomenclatural list is now-a-days open to criticism, were we disposed to be critical on this subject. But in the main the author appears to have steered a fairly middle course between extreme innovations and old-fashioned views. In one case he is clearly wrong—namely, in calling the marten *Martes sylvatica*, and restricting *Mustela* to the polecats and weasels. In birds, we are glad to see he employs genera mostly in a wide sense, so that the blackbird and ouzels appear in the same genus as the song-thrush. But these are details in which his readers have probably little or no interest, and which his critic may therefore leave alone.

If we might suggest an improvement, it would have been to curtail the amount of space devoted to the sperm-whale, which scarcely comes under the designation of a British animal, and to give more details with regard to some of the smaller mammals. For instance, a little more might have been added as to the colour-changes of the squirrel, and the distinctive coloration of the tail of the British form; while further information as to the black variety of the water-vole being restricted to damp localities might have been desirable. Perhaps, however, the author is better acquainted with the tastes of his readers than is his critic; and personally we confess to much more interest in reading the anecdotes relating to ambergris than we should in wading through details of coloration of fur and feathers—important as these latter undoubtedly are in their proper place.

As regards paper, type, illustrations (from the facile pencil of Mr. Lodge), and freedom from misprints, the volume appears all that can be desired. As an Easter gift to friends, whether young or old, interested in the natural history of our own islands—which is the proper commencement of zoological studies—no volume could be more appropriate. R. L.

OUR BOOK SHELF.

Canada's Metals. By Prof. Roberts-Austen, C.B., D.C.L., F.R.S. Pp. 46. (London: Macmillan and Co., Ltd., 1898.)

THE address which Prof. Roberts-Austen delivered at the Toronto meeting of the British Association last year, and afterwards repeated at the Imperial Institute, was so well received on each occasion that there must be many who will welcome its appearance in book form. The main object of the address was to indicate the nature and distribution of Canada's mineral wealth; but, to lend additional interest to the subject, and afford a base for experimental illustration, a specific metal—nickel—which is especially Canada's own, was given the most prominent place in the discourse.

How great is the mineral wealth of the Dominion is understood by all who know the work and publications of the officers of the Canadian Geological Survey. Report upon report have been published on the mineral resources of the various provinces, but they have mostly gone unrecognised in England, and British efforts have been tardy in developing the riches in Canadian territory. Ten years ago Dr. Dawson published his exhaustive and glowing report on the mineral wealth of British Columbia, in which he pointed out the richness of the region in auriferous deposits, and stated that alluvial gold would probably be found in the bed of every tributary of the Yukon. Had British capitalists known how to value reports of this character, they would long ago have developed the Yukon basin instead of waiting until the success of placer mining at Forty Mile Creek in 1896 called public attention to the extraordinary richness of the district in precious metals. The facts brought together by Prof. Roberts-Austen will, however, help to make the extent and variety of Canada's mineral deposits better known than they have been, and will also show that, large as is the output at the present time, it will certainly be enormously exceeded in the future.

From the general subject of Canadian mineral resources, and the need for their development, Prof. Roberts-Austen passes to a particular metal—nickel. The splash of a falling marble which is dropped into milk, and of a gold bullet dropping into molten gold, is shown, by means of reproductions of photographs, to bear a resemblance to the splash produced upon armour plates by projectiles. To prevent the marble from entering the milk, the surface of the liquid might be hardened by freezing it. Using this illustration, Prof. Roberts-Austen ingeniously explains that in a similar way an armour plate should have a face of rigid steel to break up a projectile, and a tough back to save the plate from fracture. These conditions are obtained by the addition of 4 or 5 per cent. of nickel to steel.

There are many curious points connected with the relations of iron and nickel, and several of scientific interest are described in the present volume. Every one interested in the properties of metals, or desirous of obtaining a concise and trustworthy account of Canada's mineral riches, should read what Prof. Roberts-Austen has to say upon these subjects.

Hann, Hochstetter, Pokorny—Allgemeine Erdkunde, Fünfte, neu-bearbeitete Auflage. II. Abtheilung: Die feste Erdrinde und ihre Formen. Von Ed. Brückner. Pp. xii + 368. (Wien: F. Tempsky, 1898).

In undertaking to produce a new edition of Hochstetter's share in the *Allgemeine Erdkunde*, Prof. Brückner very wisely determined to rewrite the whole section, and so to bring it into line with contemporary methods and results. The scope of this treatise on the crust of the earth and its forms includes a sketch of petrography, geological structure, stratigraphy, the agencies which work on the earth's surface (classed as endogenous and exogenous), the forms of the crust, and the morphology of the land-surface.

Prof. Brückner follows Richthofen and Penck for the most part; but his range is wide, and he pays due regard to the work of British and American geologists. It is particularly noteworthy that an authority who knows the Alps so well should refrain from making them the main source of his illustrative examples. In speaking of the interior of the earth the author leans to the view of the central part being in a gaseous state, the gaseous rock being reduced by intense pressure to a higher density than any liquid known on the surface; but he quotes and very impartially discusses the more generally accepted view of a solid earth due to the raised melting-point of rocks under pressure. Earthquakes are treated at some length; but the work of Milne is not referred to, Rebeur-Paschwitz being the principal modern authority cited. In discussing the origin of land-forms, more weight is given than in most text-books with which we are familiar to the importance of tilted or vertically displaced blocks of crust, and relatively less importance is attributed to folded structures. In treating of the *régime* of rivers and the classification of land-forms, Prof. Brückner follows Penck closely.

A number of useful references are given to special works treating on the special departments under notice; and it is gratifying to find a fair proportion of English books amongst those cited. In speaking of caverns, however, the author fails to mention M. Martel's important researches, or to refer to the Speleological Society. The revision of the work is very thorough; the only serious misprint of proper names we have noticed is the citation of the author of the *Mundus Subterraneus* as "Kirchner" in place of "Kircher."

This important work, so well-written by a master of his subject, is simply one amongst many German books on physical geography, a class still very poorly represented in the English language. H. R. M.

Elementary Botany. By Percy Groom, M.A., F.L.S. Pp. x + 252. (London: G. Bell and Sons, 1898.)

In his preface the author explains that his object has been "to place the subject before elementary students in such a way as to exercise to the full their powers of observation, and to enable them to make accurate deductions for themselves from the facts which they observe." The book is written on the assumption that a compound microscope is not employed; and in the section on physiology no knowledge of the histology of plants is assumed. There are already numerous books more or less suitable as guides to the student of elementary botany, some of them so excellent as to leave little, if anything, to be desired in their special fields. But they either omit a good deal that might readily enough be examined and verified even by beginners, or they require such a use of the compound microscope as is scarcely practicable in the teaching of botany in schools. A book on the lines indicated by Mr. Groom should prove very helpful alike to beginners and to teachers, and would doubtless be welcomed if felt to be the result of adequate personal experience. But we cannot altogether congratulate the author on his success in carrying out his objects, despite the merits of his work, especially if it is intended as a school-book. Children can scarcely be expected to benefit as much from the study of general morphology as from the examination of selected plants, in which they could observe and gradually become familiar with the various structures and life-histories.

The definitions of terms are at times scarcely in keeping with general usage; for example, those of *compound leaves*, *æstivation* and *vernation*, and *compound fruits*. It may be questioned whether the statement—"that portion of a single flower which persists after fertilisation until the seeds are ripe is termed the fruit"—is preferable to the usual definition. The classification of fruits also is unsatisfactory.

Such a statement as that "a root can only produce as lateral members branches like itself" is misleading, and indicates want of care. The production of buds by roots can easily be verified; indeed, the author refers to their growth on roots under "adventitious shoots."

In the physiology a knowledge of chemistry is assumed to an extent beyond what is to be looked for in many schools. In consequence a good deal of this section could be little more than words to those for whom the book seems to be intended. The plants treated of all belong to the flowering plants, though there seems no good reason why representatives of the larger cryptogams should not find a place in such a work. But the task of a censor is unpleasant; and although it has been necessary to criticise what must impair the usefulness of the book, we gladly recognise that it should often be found suggestive by teachers and others possessed of sufficient knowledge to avoid being misled where the risk exists. The book is well printed, and is of very convenient size, and the illustrations are good and numerous; but it would have made them more useful had some of them been repeated where more than once particularly referred to and explained. References to figures, sometimes many pages back, are apt to be irritating.

Alembic Club Reprints. No. 13. *The Early History of Chlorine.* No. 14. *Researches on Molecular Asymmetry.* Pp. 46 and 48. (Edinburgh: W. F. Clay, 1897.)

The first of these reprints contains translations of papers by Carl Wilhelm Scheele (1774), C. L. Berthollet (1785), Guyton de Morveau (1787), and J. L. Gay-Lussac and L. J. Thenard (1809). This volume, together with the earlier reprint in this series (No. 9), containing Davy's researches, completes the history of chlorine from its discovery by Scheele to the proof of its elementary nature by Davy. The importance of this discussion upon the development of chemistry is obvious, but it is somewhat difficult to step back from what is now common-place knowledge, to the standpoint of these early pioneers. The paper of Scheele, although worded in terms of the theory of phlogiston, is remarkable for its terseness and lucidity, and for the clear and correct ideas expressed upon the nature of the new gas. Indeed, if the word hydrogen be substituted for phlogiston, Scheele's explanation of the action of hydrochloric acid upon the black oxide of manganese almost represents our present knowledge. Berthollet, on the other hand, writes very voluminously upon a very slender experimental basis, and as an ardent exponent of the views of Lavoisier, concludes that chlorine gas is the oxide of an unknown radical, and this fixed idea leads to quite erroneous interpretations of observed facts.

That the effect of a preconceived idea, however, is not always prejudicial, is shown in the two lectures by Pasteur on Molecular Asymmetry, which form the contents of the second of the reprints under notice. Here Pasteur distinctly states that but for his preconceived idea as to the inter-relation of hemihedry and rotatory phenomena, he would not have discovered the opposite hemihedry of the paratartrate and tartrate of soda and ammonia; a difference missed by so careful an observer as Mitscherlich.

The English translation of these famous lectures possesses all the charm of the original. In them we have a complete account of Pasteur's work on optically active compounds, and, as the editor states in the preface, it is remarkable that the three ways of separating optical isomers here described are still the only ones known, and that there is scarcely a statement which would be changed if the whole were to be written to-day.

Practical Toxicology for Physicians and Students. By Prof. Dr. Rudolf Kobert, late Director of the Pharmacological Institute, Dorpat, Russia. Translated and edited by L. H. Friedburg, Ph.D. Pp. xiii + 201. (New York: William R. Jenkins, 1897.)

THE work before us is a translation of a book by Prof. Kobert, the second edition of which was issued in 1887. While the author was engaged upon his "Lehrbuch der Intoxicationen," by which he is for the most part known in this country, and with which the present work must not be confused, he allowed the latter to run out of print. In 1894 he wrote the third German edition, and it is this which Dr. Friedburg has now translated and edited, three years after its issue. As we have not had the opportunity of seeing the third German edition of the original, we are unable to measure either the quality or extent of Dr. Friedburg's editing. With regard to his translating, it is the worst which has ever come under our notice. In fact the English language, in Dr. Friedburg's hands, is extremely difficult to understand. As this is a very strong statement it behoves us to give an instance, which, by the way, is not the worst we could find. Dr. Friedburg is speaking of a rise of blood pressure of peripheral origin. "If this is the case, the rise must obtain after the injection of the poison into the blood of an animal even if the marrow of the neck has been cut through and whose spinal marrow has been drilled out." We quote this instance, since it shows that the author is not only deplorably ignorant of the English language, but has no knowledge of the English equivalents of German physiological expressions. Dr. Friedburg's Latin is no better than his English; the plural of vagus is always written "vagii," and so polymorphic is the declension of this noun that we find the nominative singular written "vagis."

To turn from the manner of the book to the matter, it is undoubtedly full of information, and, if properly translated by some one acquainted with pharmacological method and the English language, would be valuable to both the pharmacologist and toxicologist. F. W. T.

What is Life? or, Where are we? What are we? Whence did we come? and Whither do we go? By Frederick Hovenden, F.L.S., F.G.S., F.R.M.S Pp. xiv + 290. (London: Chapman and Hall, 1897.)

MANY matters are dealt with in this book, ranging from the stellar universe to cell structure. About half the text is made up of quotations from the writings and utterances of men of science, distinguished and otherwise, and the remainder consists of perplexing conclusions which the extracts are held to support. Excessive zeal is shown in establishing fundamental truths, but that may be forgiven. It is when the author expands into the ether, so as to embrace in his comprehensive idea such diverse subjects as the Pentateuch and the currency question, that we lose the connections of the argument. The chief conclusions arrived at are stated in the following words:—

"From the combining power of the strongest species of atoms under the influence of Ether, arises the formation of cells.

"Cells under the influence of the strongest cell group themselves to form highly complex structures or organisms, hence the most complex of all organisms—Man. The activity of cells forms that activity we call Human Life. Thus Life is the sum of the activity or energy of molecules formed of atoms.

"The power of the regeneration of molecules causes regeneration of cells, and this causes regeneration of Life. Life is eternal."

La Tuberculose et son Traitement hygiénique. Par Prosper Merklen, Interne des hôpitaux de Paris. Edited by Felix Alcan. Pp. 190. (Paris: Ancienne Librairie Germer, Baillière et Cie.)

THIS little book forms No. cxix. of the "Bibliothèque Utile" series, and is certainly calculated to serve a useful purpose. It addresses the public, and not the medical profession. The nature of tubercular disease is very clearly and accurately set forth in plain language, together with its chief manifestations in man, and the principles underlying its prophylaxis and treatment. It is indisputably true that in the case of a preventable disease like tuberculosis, which constitutes one of the main scourges of civilised man, a dissemination of sound knowledge on the subject is the first necessary step in educating public opinion up to the hygienic requirements and sanitary restrictions which are demanded to check its spread. The present brochure is a creditable effort in this direction: the author has succeeded in placing home truths on the subject in a very clear light, and his remarks cannot fail to be of direct benefit to the public.

Marriage Customs in Many Lands. By the Rev. H. N. Hutchinson, B.A., F.G.S. Pp. xii + 348. (London: Seeley and Co., Ltd., 1897.)

MR. HUTCHINSON, forsaking geological subjects for a time, presents in this volume a purely popular account of the quaint customs connected with marriage in many parts of the world. He has not attempted to discuss the scientific questions relating to the history and origin of human marriage, but has merely aimed at providing the general public with readable descriptions of curious nuptial ceremonies of various peoples and races. The readers for whom the volume is intended will find much to interest and amuse them in it; and the excellent illustrations—among the best of their kind—give the book additional attraction. Authorities may not agree with all Mr. Hutchinson says; but, as the book is a compilation, the mistakes are usually the mistakes of the sources from which the information has been derived, and the only criticism that can be offered is whether the author has exercised sufficient discrimination in the collection of material.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

Misleading Applications of Familiar Scientific Terms.

May I, not as an expert in science, but as one who has made some research into the conditions of lucidity, venture to thank you for the protest which appears in your current number against a misleading application of the familiar term "Light"? This is not of course the only instance of the kind; but it seems especially regrettable as tending, by the very success and popularity of the Lectures reviewed, to introduce gratuitous confusion into youthful minds.

I may perhaps be pardoned for adding that I was fortunate enough in my little book, "Grains of Sense," published last year, to anticipate the verdict of your reviewer, and to point out how much, in this and similar cases, such modes of expression on the part of scientific men tend on the one hand to diminish our precious and too slender store of clearness of thought, and on the other to hinder the progress of science itself.

V. Welby.

April 1.

The Kinetic Theory and Radiant Energy.

In the course of the discussion which took place in your columns during the winter of 1894-5 on the kinetic theory of gases, emphasis was rightly laid on the difficulty of reconciling the law of partition of energy among the different degrees of freedom of molecules of gases with the large number of such degrees of freedom indicated by their spectra, and, generally, of explaining, on the kinetic theory, the relations between matter and the ether required to account for radiation. It was even suggested, by one writer, that the ether, with its vastly larger number of degrees of freedom, must ultimately absorb all the energy of the molecules. I instanced the case of a sphere moving in an infinite mass of perfect liquid as exemplifying a system where no such ultimate absorption of energy would take place, and pointed out that everything depended on the laws according to which transference of energy took place between the molecules and the ether.

The object of this letter is to show that the subsequent discovery of the Röntgen rays has suggested a theory of the radiation of heat which may possibly throw considerable light on the difficulties referred to by affording an answer to the question, "If the temperature of a gas is proportional to the mean translational kinetic energy of the molecules, how comes it that this kinetic energy can be transferred from one set of molecules to another by radiation through the ether?"

Consider the Röntgen rays: we know, firstly, that they are produced by the impact of the kathodic rays on the Crookes' tube, these latter consisting not improbably of streams of bombarding molecules; secondly, that they not only have the power of discharging electrified bodies, but also of modifying the electrical state of gases in such a way as to enable these to discharge bodies. In this modified air, to which Villari has applied the somewhat barbarous name of "aria Xata" or "xd. air," some kind of dissociation of the electrons must necessarily have taken place.

Arguing from analogy the idea suggests itself that the encounters between molecules of a gas, no less than the kathodic bombardments, may give rise to radiations, and these, too, when falling on another mass of gas may modify the electrical state of its molecules in such a way that their original electrical state is only restored by encounters between them.

Now taking, as a simple illustration, two oppositely electrified perfectly elastic conducting spheres; as these approach one another, they acquire kinetic energy in virtue of their attraction. On coming into contact they are discharged and the attraction ceases, so that their kinetic energy of separation is greater than that which they had previously to coming within each other's influence. Again, when a charged and an uncharged body impinge, the charge is distributed between them; they repel one another as they separate, and again acquire an increase of kinetic energy—as in the ordinargy pith-ball experiment.

It follows that the incidence of rays possessing the property suggested above will tend to increase the temperature of a gas.

The discharge which takes place at an encounter will, however, be an oscillatory one, and will lead, therefore, to further generation of undulatory rays.

Considering two masses of gas at unequal temperature, the impacts in the hotter gas, being the more frequent and violent, will give rise to the more copious emission of rays, and these falling on the cooler gas, will produce the greater electric dissociation resulting in the greater acquisition of kinetic energy in collisions between the molecules. The feebler rays from the colder gas will have less effect on the molecules of the hotter one, and the kinetic energy supplied in this way will not compensate for that lost by radiation. Thus the "theory of exchanges" will hold good.

A still more important consequence of such a theory is that no interaction will take place between the ether and molecules except where there are encounters between the latter, and, moreover, the interactions which occur in an isolated mass of gas will not affect the translational velocity of its centre of mass, nor the angular momenta about axes through its centre of mass. Thus it results that the celestial bodies go on in their course experiencing no resistance whatever from the ether.

On the other hand, the fact that light from distant stars is not absorbed before it reaches the earth, no longer implies the complete absence of matter in interstellar space. Isolated molecules will absorb no energy from the ether; and so long as the molecules moving about in interstellar space are assumed to be so few and far between that collisions practically never occur, there will be nothing to impede the passage of light or heat rays. It is only when such rays fall on assemblages of molecules sufficiently dense to possess the attributes of what we call *matter*—as, for example, when they reach our atmosphere—that absorption of energy will take place.

The phenomena of irreversibility and of degradation of energy would thus, so far as the present view goes, be restricted to material bodies, and hence the conditions necessary for the existence of life on our earth may have been brought about without the enormous waste of energy which would be required in the absence of *some* such theory.

A photo-voltaic theory of photographic action formed the subject of exhaustive experimental investigation at the hands of Herr Luggin last year, and photo-voltaic theories of vision have also been proposed. It would thus seem that the analogy between the action of heat rays, visible-light rays, ultra-violet rays and Röntgen rays may be complete. The question still remains, *how* are ethereal waves able to affect the electric state of assemblages of molecules? But since Röntgen-ray physicists have proved that they do this, the question has to be faced in any case. It is now rendered no more difficult, and, on the other hand, our theories of the relations between ether and matter are simplified by referring radiation of heat to the same phenomenon.

G. H. Bryan.

Note on Mr. Wood's Method of Illustrating Planetary Orbits.

I fear that Mr. Wood's beautiful method of illustrating planetary orbits by means of a bicycle ball rolling on a glass plate about the pole of an electro-magnet (Nature, April 29, 1897), has rather fallen into disrepute in the minds of many physicists since its criticism by Mr. Anderson in Nature, May 13, 1897. Mr. Anderson there states that the law of attraction in such a case would be that of the inverse fifth power of the distance. This could only be true if the ball were of very soft iron. A bicycle ball is far from this, and becomes strongly magnetised after brief use in the experiment, behaving like a permanent magnet of great coercive force. Under these conditions the attraction between the pole and the ball will vary approximately as the inverse third power. There is also another factor to be considered. If the true pole lies below the glass plate, only a certain component of the total force is active in producing the attraction towards the centre of motion. To determine what the law of variation of this component will be, I have had one of my students take a number of series of observations on the attraction of a bicycle ball along a plane perpendicular to the axis of a magnet.

In the experiments the magnet was horizontal, and the bicycle ball with its magnetic axis vertical was fastened to one end of a strip of spring brass, the other end of which was clamped fast in a sliding clamp so as to be raised and lowered. The bending of the brass strip under the attraction of the magnet on the ball was measured by means of a telescope and scale, the mirror being fastened to the end of the strip. As the motion of the ball was entirely in a plane perpendicular to the axis of the magnet, the law of variation of force must have been very nearly the same as in the orbit experiments.

When the ball was directly over the true pole, which lay about 1 cm. from the end of the conical pole-piece, the law was nearly that of the inverse cube, the observations being taken between the limits of 3 cm. and 14 cm. from the axis of the magnet. Other series were taken with the plane of motion of the ball at different distances from the pole, and it was found that with the plane of motion at 2·8 cm. from the true pole the law of the inverse square was very closely obeyed between 4 cm. and 14 cm. from the axis. These limits cover the region in which the orbits would in most cases be formed. The exact law of force as determined by least squares from seven observations between the above limits was that of the 2·1 power of the distance.

An Extraordinary Heron's Nest.

I SEND you a photograph of probably the most extraordinary heron's nest ever discovered in this or any other country. During a gale it was blown from the top of an elm tree in the heronry on Stoke Hall estate in Notts, the seat of Sir Henry Bromley, Bart. It is of unusual size, and almost exclusively composed of wire of varying lengths and thickness; the centre, or "cup," alone being composed of fine twigs, grasses and feathers. Several other nests of the heronry, which had also been blown down, contained pieces of wire cleverly worked in with twigs in the usual way, but this was the only one entirely composed of that material, as far as the main structure is concerned. There are happily now a very flourishing heronry at Dallam Tower, Westmorland, the seat of Sir Henry Bromley's son, Mr. Maurice Bromley-Wilson, and although I have been familiar with it "off and on" for very many years, and with several other heronries in various parts of the country, I never knew of the birds using wire in the construction of their nests. I have several records of rooks using wire in large quantities in the construction of their nests. Particulars of one very remarkable instance were published in the *Yorkshire Weekly Post* of May 19, 1894, and of another in the same paper for June 23, 1894. Both of these freaks took place in India: one at Calcutta, the other at Rangoon. The other curious feature of the Stoke Hall phenomenon is that there is, and never has been, any lack of ordinary building material, and that all the wire used must have been carried a great distance.

"The Story of Gloucester."

REFERRING to your article (p. 221), I think you cannot have looked at pages 70 to 117 of the Gloucester Small-pox Epidemic Blue Book, by Dr. Coupland. I have analysed all these cases, and here is the result.

Description.	Cases.	Deaths.	Deaths per cent. of cases.
"*Unvaccinated*"— These contain 21 cases, 10 deaths, whose description includes the word vaccination or vaccinated	679	287	42·2
"Vaccinated in infancy," no description of vacc. marks ...	788	91	11·5
Do. "no marks," very abundant small-pox eruption	35	13	37·1
Do. "one" vacc. mark	30	3	10 0
Do. two do.	100	10	10·0
Do. three do.	141	13	9·2
Do *4, 5, 6, 7 and 8 vacc. marks*	197	13	6·5
Do. (?) v. marks, very abundant eruption	9	4	44·4
Totals	1979	434	21·9

The accepted fatality before Jenner's birth was ... 16 6

There were—	Cases.	Deaths.	
Re-vaccinated cases at Gloucester	173	9	5·2

These had all kinds of v. marks *up to 8 in number*, and some had been *repeatedly* re-vaccinated; one "often" re-vaccinated. If the same energy had been put into a critical proof of the vaccination of each one as was into avoiding condemning vaccination, there would be little to show, even in fatality, in the above *for* vaccination; as it is, it kills *every* vaccine dogma.

ALEX. WHEELER.

MR. WHEELER, it must be assumed, is wishful to prove that the fatality amongst the vaccinated is as high, or at any rate is not lower than amongst the non-vaccinated. It is surely not necessary for him to separate vaccinated cases into those "with marks" and those with "no marks," since to him it should be immaterial whether a patient be vaccinated or not.

Taking Mr. Wheeler's own classification, we find that of the unvaccinated cases, 679 in number, 287 died, giving a percentage mortality of 42·2; whilst of the vaccinated cases, 1300 in number, only 147, or 11·3 per cent., died. These figures should surely be enough to settle the question as regards percentage mortality, and the mere inclusion of the 21 cases and 10 deaths, whose description includes the word "vaccination" or "vaccinated," does not in any way invalidate the general conclusions to be drawn from these figures.

If now, however, a class for the "under-vaccinated" be included, the second class may be divided into "under-vaccinated" 89 cases with 27 deaths, or 30·3 per cent., and vaccinated 1211 with 120 deaths, giving a mortality of only 9·9 per cent. It is evident that Mr. Wheeler's table in no way conflicts with the figures given in the Report (except in one small particular, noted below), but is based on a misconception of the term "under-vaccination" as used by Dr. Coupland, who used the term to signify those cases of small-pox which had undergone vaccination at any time within the (generally accepted) period of incubation: *i.e.* fourteen days before the appearance of the rash. In the list of "unvaccinated" cases are included a few which were actually vaccinated in the invasion period. No doubt some of these should be placed in the vaccinated class; but others, again, should be grouped in the unvaccinated class. The Royal Commission reckoned the whole group, instead of a large proportion, in this latter class, which is perhaps not strictly scientific and accurate. Mr. Wheeler, however, goes far further astray in including them all in the vaccinated class, which is clearly erroneous. It may be pointed out in this connection that, in his recently published work, Dr. Cory gives some most interesting facts which tend to show that vaccinal immunity is not obtained until nine days have elapsed after inoculation. It would be easy, therefore, from the table on page 149 of the Report, to divide the total 89, there reckoned as "under vaccination," into two sections: (*a*) those vaccinated before, and (*b*) those vaccinated within eight days, of manifesting small-pox. If this were done, there would be added (*a*) to the "vaccinated" class 10 cases with 3 deaths; and (*b*) to the "unvaccinated" class 79 cases with 24 deaths.

Without checking Mr. Wheeler's figures by laboriously going through pages 70–117 of the Report, it is simply necessary to deduct those "under-vaccinated" from his several lists. His classes of "no marks" and "? marks" correspond with Dr. Coupland's groups of "alleged" and "doubtful" vaccination, except that Dr. Coupland's figures give one case less and one death more than Mr. Wheeler's. Although it is highly probable that many of these uncertain and doubtful cases were really unvaccinated, the Report includes them, as does Mr. Wheeler, in the "vaccinated" class (see page 153, &c.).

MR. WHEELER'S FIGURES DISTRIBUTED ON PLAN OF REPORT.

Mr. Wheeler's table.				Vaccinated.		"Alleged" vaccination (no marks).		Doubtful vaccination.		"Under" vaccination.		Unvaccinated.		—

		Fatality ...		...	8·7	—	40·0	—	66·6	—	30·3	—	42·2	—	21·9

* Discrepancy due to inclusion by Mr. Wheeler of one death too many among "vaccinated in infancy," and one case too many among the "? vaccinated."

It is difficult to grasp Mr. Wheeler's point in presenting the figures in this way. It might be useful if these questionable cases had all been turned over to the "unvaccinated" class; but why does he detach them from the rest of the admittedly vaccinated? He could not have intended to show, as his own figures do, that post-vaccinal fatality diminishes with a rise in the presumed greater efficiency of vaccination as evidenced by the number of scars. Dr. Coupland does not enter into the question of marks. It has been done over and over again, and in both his Dewsbury and Leicester Reports Dr. Coupland makes a most valuable contribution to this question. The main object of the inquiry at Gloucester was to determine the broad question of the occurrence and fatality of small-pox in the vaccinated and unvaccinated.

Perhaps the most important point that the Gloucester epidemic illustrated is one that is passed over by Mr. Wheeler, and one which unfortunately appears as though the opponents of vaccination in their pursuit of a fad had become callous to the fate, in this instance, of the Gloucester children, but also of the children wherever there is an outbreak of small-pox.

About the effects of the vaccination or non-vaccination of children there can be no dispute. In this connection it is only necessary to refer to the figures of those attacked between one and ten years of age, and especially at the incidence rates given near the end of the Report. Indeed, if only those households are taken in which some vaccinated children are to be found, it appears that the incidence of small-pox *among the vaccinated children* was only 10 to 100, though amongst their unvaccinated brothers and sisters it was 10 to 14; whilst the death rate (per 1000 of those exposed to infection) was for the vaccinated less than 4, for the unvaccinated 255; this, too, in families of the same class, in the same streets, and living under similar sanitary (or unsanitary) surroundings as those in which every child was unvaccinated. May we not legitimately infer that had all the Gloucester children at these ages been vaccinated, only 1/7th of those that did suffer would have suffered, and the mortality would have been less than 1/60th of that to which it did attain? Vaccinators are said to be incapable of viewing this subject impartially, but Dr. Coupland is most judicious in the handling of his figures, and it is apparent that the evidence that he has collected from careful observation weighs with him as much or more than do the figures he has brought together; and it is certain that if those who deny the efficacy of vaccination could have the experience that he has had, they would cease to hold the view that he is prejudiced. Any one who considers his Report judicially must confess that he has presented the facts extremely fairly and impartially, and that he evinces far less bias than those who, on very slight and shadowy information, are undoubtedly unreasonably opposed to vaccination—the very people, in most cases, who bring the charge of partiality. Every one knows that where large numbers of statistics have to be collected, errors of fact may creep into records, and that, with fuller knowledge, slight modifications may have from time to time to be made. As regards the main facts of Dr. Coupland's records, however, the most exacting will find it difficult to trace any important inaccuracy. In respect to the records concerning children the facts are indisputable, and lead to the mournful conclusion that amongst these there would have been vastly less suffering and far fewer deaths in the Gloucester epidemic, had not infant vaccination been so widely neglected.

As regards re-vaccination it is difficult to see how Mr. Wheeler obtains the figure 173. In the table (p. 46) there are given 190 who were stated to have been re-vaccinated. Assuming that each of these was really and efficiently re-vaccinated—a large assumption—the fatality would be 4·7, or much below the general vaccination rate. There are, however, several difficulties to be surmounted before a satisfactory demonstration of the relationship of re-vaccination to small-pox can be arrived at; and one of these especially, that of the true interpretation of a failure "to take," is a most important one. This failure "to take" does not necessarily imply that the subject is immune. Then there is also the fallacy of recent re-vaccination which, like recent primary vaccination, may have been done too close to the date of the onset of small-pox to have any influence on the disease (see following table):—

Small-pox in the "Re-vaccinated."

190 persons who were *stated to have been* re-vaccinated were attacked by small-pox. Of these:

(*a*) 52 were "re-vaccinated" at various periods prior to epidemic, in some cases several years.

In 37 this re-vaccination was stated to have been successful, and 2 of these patients died.
In 15 this re-vaccination did "*not take*"—1 died.

(*b*) 30 were "re-vaccinated" between 3 months and 14 days of the attack of small-pox.

In 8 the vaccination "took."
In 22 ,, ,, "*did not take.*"

(*c*) 108 were "re-vaccinated" within 14 days of appearance of small-pox eruption, some of them even in early days of attack.

In 83 vaccine vesicles appeared—4 died.
In 25 the vaccination *did* "*not take*"—1 died.

Where Re-vaccination believed to have been successful.

(*a*) 37 cases—2 deaths—fatality 5·4 per cent.
(*b*) 8 ,, 0 ,, ,, *nil.*
(*c*) 83 ,, 4 ,, ,, 4·8 per cent.

Where Re-vaccination known to have been unsuccessful.

(*a*) 15 cases—2 deaths—fatality 13·3 per cent.
(*b*) 22 ,, 0 ,, ,, *nil.*
(*c*) 25 ,, 1 ,, ,, 4·0 per cent.

Or of whole number, 4·8 per cent.; or if we take whole number (190), irrespective of date or of success, a fatality of 4·7 per cent.

Mr. Wheeler's statement that the accepted fatality before Jenner's birth was 16·6 has very little bearing on the question, since the epidemic at Gloucester gave 21·9, and this, including the 42·2 per cent. unvaccinated fatality at all ages, which is less than that between 1 and 10 years, the period of most fatal small-pox, in the pre-vaccination days. The Gloucester outbreak was undoubtedly unusually virulent; but, surely, equally severe epidemics are on record.

THE WRITER OF THE ARTICLE.

THE SOUTH KENSINGTON SCIENCE BUILDINGS.

WE are glad to see that the various important matters connected with the extraordinary proposal to spend some eight hundred thousand pounds in interlacing the Science with the Art buildings—chemical laboratories with picture galleries—are being considered by a Parliamentary Committee. This is more especially desirable, since, as we have previously pointed out, it is stated that about half the money proposed to be spent is sufficient for present needs.

The *Times* gives the following account of the meeting of the Select Committee on Friday last, Sir F. S. Powell presiding. Sir John Donnelly, secretary to the department, was further examined. Sir H. Howorth said it would be of great assistance to the Committee if they could get from the officials of the department an expression of their views as to the changes which were desirable or were not desirable in regard to the housing of the Science and Art collections. The witness said that was rather an awkward question; he really did not think it would be proper for him to volunteer any statement which might conflict with the present proposals of the Treasury and the Board of Works. He had already stated that, in his opinion, the Science collections should be on the west side of Exhibition Road and the Art collections on the east side. He believed that that was the proper solution of the South Kensington question, and he had seen no reason in what had taken place since he gave expression to that view to change his opinion. Sir H. Howorth: Mr. Akers Douglas has stated that, with the removal of the residences and of the secretarial offices to Whitehall, the Government find that they will have at their disposal a much larger space than had been previously contemplated, and that therefore they will be able to put the Science and Art collections on the one side of Exhibition Road. Do you think the space thus provided will be sufficient for the whole of the collections being placed together? The witness: I do not think so, and that was my reason for saying that I saw no ground for changing the opinion I have already expressed on the subject. I contemplate that the museums will increase, and I do not think it would be wise to consolidate the collections on one side of the road. In answer to further questions, Sir John Donnelly said he thought it was most desirable that the Geological Museum in Jermyn Street should be transferred to South Kensington. The library which was now in Jermyn Street would be of great value at South Kensington, and under the present system of division they had to duplicate many of the books. He would undertake to bring this view before the Lord President and the Vice-President of the Council. As to the Art side, the theory that it was better to have a large series of small rooms in which they could classify their objects rather than a series of very large halls or rooms was absolutely impracticable in their case. He was distinctly in favour of residences being provided for some of the officers—say four—either in the same buildings in which the collections were housed or very close to them. There was, he knew, a morbid fear of fire being caused when the residences were in the actual building, but he did not himself believe that this was a very great source of danger.

PHOTOGRAPHY AND TRAVEL.[1]

THE globe-trotter of to-day is almost as notorious for his poor photographs as his ancestor of the Mandeville era was for his traveller's tales. Without instruction in the technical part of his work, and without the geographical training required to teach him what to look for and how to view it, he habitually brings home productions which may be of interest as studies for an impressionist artist, but are of little or no value to the student of nature. Hence it is with particular pleasure that we welcome the republication in a generally accessible form of a selection of Mr. Thomson's magnificent photographs made in China. These were taken before the days of dry plates and snap-shots, when it was necessary to prepare and develop the plates on the spot, and to employ a camera of large dimensions not easy to transport through regions where, to say the least, strangers are not received with overwhelming hospitality.

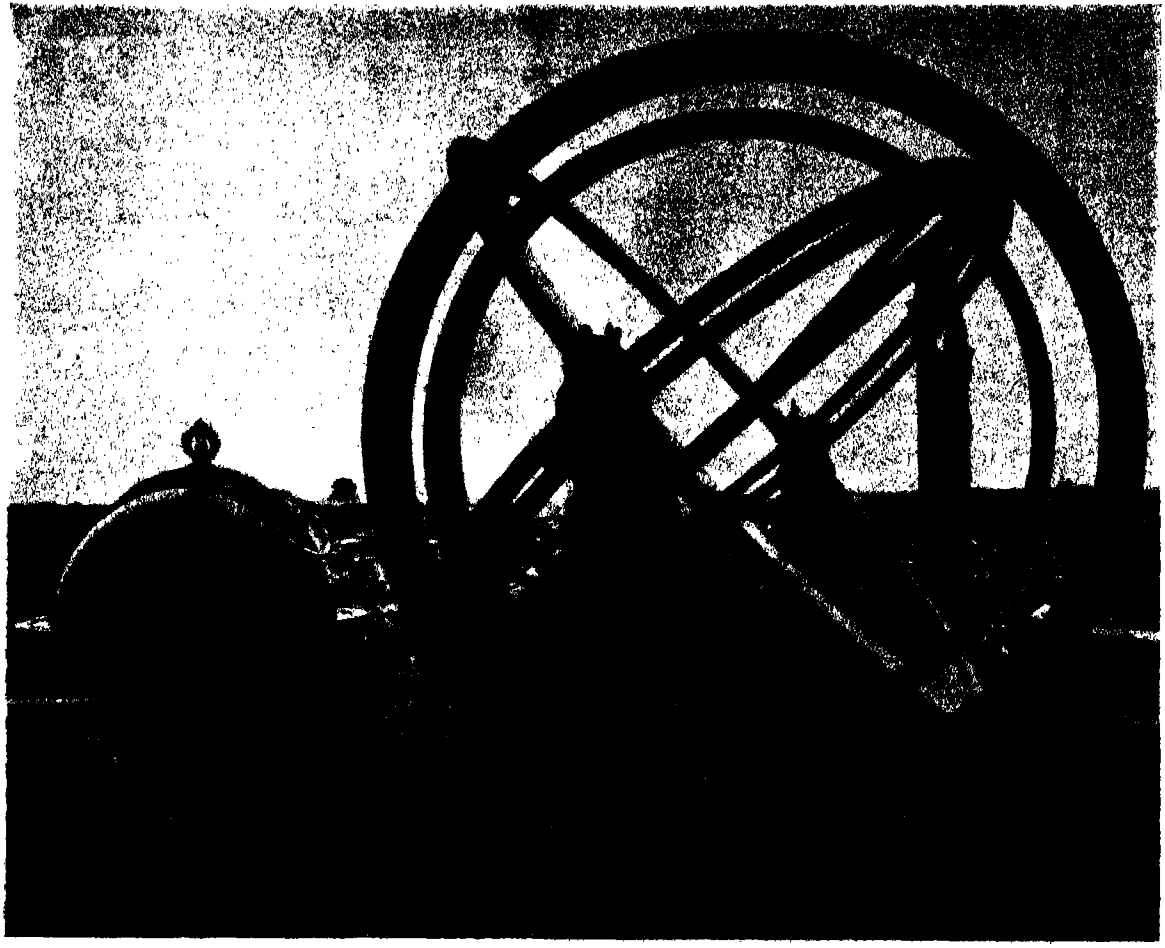
The photographs are selected so as to give a connected idea of life in China proper in all its aspects, and also to illustrate the natural scenery of many of the provinces and of Formosa. The pictures are so satisfactory from every point of view, that it is no slight to say that the letterpress takes a humbler place when one estimates the value of the book. The text for the most part is descriptive of travel, and illustrative of the photographs, incidents and anecdotes being introduced for that purpose. It would have been more useful if the exact order of the journeys and their date had been mentioned; and a map might very well have been added to show the situation of the regions visited.

Three introductory chapters deal with the condition of China now and in the past, and with the Chinaman abroad and at home. Having regard to the somewhat acute interest now being taken in China by the nations of Europe, the perusal of these chapters should prove useful; and so should the description of the various great centres of population on the coast, in the Yangtze valley and Pekin.

---

[1] "Through China with a Camera." By John Thomson, F.R.G.S. With nearly 100 illustrations. Pp. xiv + 284. Small 4to. (Westminster: A. Constable and Co., 1898.)

Not the least interesting of the photographs is that which, by the courtesy of the publishers, we are able to give here. The illustration shows two ancient astronomical instruments of purely Chinese construction, which stand on the walls of Pekin, with instruments dating from the thirteenth century, and others constructed for the Chinese Government by the Jesuit missionaries of the seventeenth century. The circles of the instruments of the thirteenth century are divided into 365¼ degrees to correspond to the days of the year, each degree being subdivided into hundredths, but the later instruments have their circles divided into 360 degrees.



Ancient Chinese Astronomical Instruments.

THE HEIGHTS OF METEORS.

It is perhaps surprising that the heights of meteors, and especially of that class known as fireballs, were not determined with any accuracy until the near approach of the present century. It is true that a few individual attempts were made in this direction but, considering the large number of brilliant meteors which appear every year, it is curious that some systematic attempts were not made at a much earlier date in this direction. It must, however, be remembered that many years ago there were comparatively few astronomical observers, that means of communication were slow, and that the importance of recording these objects as precisely as possible had not been recognised.

The present is perhaps an appropriate period to refer to this subject, for it was in 1798, just a century ago, that the first systematic attempt was made (by Brandes at Leipzic, and Benzenberg at Dusseldorf) to determine the heights of meteors. Schröter had in 1795 seen a shooting-star (in his reflecting telescope of 20 feet focus), the height of which he estimated at more than four millions of miles! Brandes and Benzenberg, however, found from 22 meteors which they mutually observed in 1798, heights varying between 6 and 140 miles. Brandes instituted some further observations in 1823, and of 62 meteors available for calculation 55 were found to have heights between 30 and 70 miles. On August 10, 1838, M. Wartmann, at Geneva, followed up Brandes's inquiries, and derived the average height of the meteors seen on that occasion as 550 miles, and their velocity 240 miles a second. These values, compared with modern observations, were far less accurate than Brandes's earlier ones.

It is not proposed in this paper to deal fully with the average heights of meteors, for that has been discussed by several authorities. The values are about 76 and 51 miles respectively for the mean elevations at appearance and disappearance. In the case of fireballs, however, they penetrate much deeper into our atmosphere than the ordinary shooting-stars, and their heights at extinction appear to be about 30 miles. For the present purpose it is intended to refer to the elevation of these objects at the beginning of their visible flights, for this elevation is so considerable in some cases, that, if atmospheric friction induces their combustion, the air extends to a much greater distance from the earth than is ordinarily supposed.

It is not at all a rarity to find meteors which, at the instant of their first appearance, were more than 100 miles in height. I have looked through various lists of the computed real paths of fireballs and shooting-stars, and find that, out of 577 cases, 116 exhibited a beginning height of 100 miles or more, the average being 130 miles. In fact, one meteor out of five displayed incandescence *when 100 miles or more from the earth's surface.* The materials from which I obtained these results were by Dr. E. Heis, Prof. A. S. Herschel, Prof. G. von Niessl, and myself. The most extreme heights[1] were :—

Date of meteor.	Height at beginning. Miles	Authority.
1868 September 5	483	G. von Niessl.
1849 August 11	216	E. Heis.
1861 July 16	195	A. S. Herschel.
1862 February 2	190	,,
1864 August 10	188	E. Heis.
1883 June 3	188	G. von Niessl.
1861 August 10	184	E. Heis.
1864 July 28	184	,,
1870 September 27	184	G. von Niessl.
1877 March 21	184	,,

The first of these is probably erroneous, for the observations, though numerous, were not accordant, and with such data it is possible for different computers to work out anomalous results. Thus, in the instance of the very long-pathed fireball seen in France and Germany in 1868, three paths have been computed, and they differ widely in their character. These differences are induced by the erroneous observations, and the difficulty of putting a consistent interpretation upon them. The radiant point, as adopted by the various computers, is dissimilar; and this in itself must occasion a great discordance in the heights, for one observer putting the radiant 5° above the horizon will obviously obtain a lower elevation for the beginning point than another who places it 15° above the horizon—the angle of the meteor's descent being much less. In regard to the fireball of September 5, 1868, the following results were obtained :—

Height at beginning. Miles	Height at ending. Miles	Length of path. Miles	Radiant. ° °	Authority.
483	115	1770	13 — 3	G. von Niessl.
69[*]	191	1000	22 — 12	A. Tissot.
103	65—70	880	18 — 8	A. S. Herschel.

Thus, while von Niessl made it descend from 483 to 115 miles, M. Tissot concluded that it really ascended from 69 to 191 miles! Prof. Herschel's results appear to be the best that can be derived from the materials available, for he obtains normal heights and a slight ascent of the meteor just before extinction. Its enormous length of path is quite beyond dispute.

In every instance where the observations are very inconsistent, it is clear that the results of investigations of this kind must depend largely upon the interpretation put upon them. And for strictly scientific purposes the real paths derived from such materials are of little use, for any critical deductions or trustworthy comparisons cannot be made from them. The instance above alluded to furnishes, however, a very exceptional case; but it has been selected in proof of the great uncertainty attaching to deductions based upon conflicting observations.

It appears that about 20 per cent. of meteors are at least 100 miles high at the instant of their first visible apparition. This conclusion rests upon a considerable number of results, including a large proportion of fireballs, and may be trusted within small limits of error. From the materials I have examined, I believe the actual height at first appearance of a meteor is *very rarely* as much as 150 miles, and that it seldom reaches beyond 130 miles.

It is singular that in 1897 I found unusual elevations for several meteors, in fact 9 out of 26 (*i.e.* more than one-third), whose real paths I computed, indicated a beginning-height of over 100 miles. These were :—

Date, 1897. h. m.	Mag.	Height at beginning. Miles	Height at ending. Miles	Length of path. Miles	Radiant. ° °
Aug. 2, 11 5½	2	112	90	40	40 + 55
2, 11 24	5—4	139	124	28	73 + 66
8, 9 15	> ♀	133	115	63	52 + 47
9, 13 27	3—1	140	77	81	46 + 56
9, 13 52	3	131	89	56	58 + 60
9, 14 18	3 × ♀	137	75	75	44 + 45
Nov. 13, 15 28	1	125	77	75	136 + 9
13, 15 52	1	103	59	60	152 + 22
Dec. 12, 8 6	> ♀	112	19	151	80 + 23

It is possible that in several of these cases mistakes of identification may have occurred. It must sometimes happen, and especially during the occurrence of a rich shower, that two meteors are recorded at the same time at different places, which show parallax in the right direction, though they are entirely separate objects. Accidental coincidences of this kind would, however, not very often occur, and they would usually be detected by some features of mutual discordance.

There is another point in connection with the first appearance of meteors which merits attention—this is, that observers seldom secure an accurate view of it. The end point is more precisely determined as the eye steadily follows the object until its extinction. But it is rarely the case that even an habitual observer of meteoric phenomena happens to be looking directly to that point of the heavens where a meteor appears. He generally catches it after it has already traversed a section of its flight, and often estimates the extent of its backward trajectory, sometimes adding 5° or 10° to the observed starting-point. Now, a slight error in carrying the visible line of flight too far back may put 30 or 50 miles on the beginning-height of a meteor, especially if it is *anywhere near its radiant.* It would, therefore, be safer for observers to record the path actually witnessed, without assuming the extent of the portion which escaped them.

But apart from all the uncertainties (which have their outcome in the rough character of the observations) attaching to the subject, it is impossible to put aside the evidence that meteors are sometimes 130 miles and, in extremely rare instances, 150 miles high when they are first visible. There are grave doubts that any meteor has ever been visible at a height of 200 miles. And it is probable that many, if not all, of the instances where heights of about 170, 180 or 190 miles have been found, were due to the commencing points of the flights having been carried too far back by the observers, or that mistakes in the directions have led the computer to adopt erroneous radiants and deduce initial heights considerably in excess of the correct ones.

If photography could step in here, and dispel all the doubts arising from our hurried and often questionable observations, it would be a matter for congratulation. When a meteor is observed by two or more practised observers, the results usually work out very well; but in the case of large fireballs witnessed by a great number of persons, the descriptions are often very conflicting and dubious, and the discussion of such materials is seldom either profitable or trustworthy. W. F. Denning.

---

[1] Other instances of abnormal height might be quoted from the deductions of other authorities, but they are open to serious question. Thus, for the fireball of March 19, 1718, the height at first appearance has been given at 297½ miles; but Prof. Herschel finds, from a careful rediscussion of the observations, that the meteor began at an elevation of only 80 miles.

[*] This is the lowest elevation of the meteor as found by M. Tissot, and quoted in British Association Report for 1869, p. 272.

RUDOLF LEUCKART.

RUDOLF LEUCKART, whose death removes one of the most eminent figures in the zoological world, was the son of a bookseller, and was born on October 7, 1822, at Helstedt, which until 1809 had been the seat of one of the universities of the state of Brunswick. A taste for the study of natural history was probably hereditary in the family, for his uncle, Friedrich Sigismund Leuckart (1794–1843), was a zoologist of no mean reputation. The subject of our sketch began his career as an author at a comparatively early age, for whilst still a student at the University of Göttingen he completed the "Lehrbuch der Zootomie" of his teacher, Rudolf Wagner. After serving for a time as assistant in the Physiological Institute of his *alma mater*, he received in 1850 the appointment of extraordinary professor at Giessen, which the genius of Liebig had then raised to a position of great importance among the universities of Germany.

He had already shown what manner of man he was by the publication of two treatises, "Beiträge zur Kenntniss wirbelloser Thiere" (in conjunction with Heinrich Frey, 1847) and "Ueber die Morphologie und Verwandtschaftsverhältnisse der wirbellosen Thiere" (1848), in which the great division *Radiata* of Cuvier was broken up into *Cœlenterata* and *Echinodermata*. He further recognised Metazoa as divisible into six types—*Cœlenterata, Echinodermata, Vermes, Arthropoda, Mollusca* and *Vertebrata*—and thus initiated a system which, in its main features, is still maintained at the present day, and must be recognised as a stroke of genius in a young man of some twenty-five summers, working at such an early stage in the history of morphological science.

In 1855 he was made ordinary professor, and in 1870 removed to Leipzig. As a teacher he was clear and stimulating, and his remarkable success in this department of scientific work is attested by the volume issued in commemoration of his seventieth birthday, in which about 139 men of science, including many of the most eminent zoologists of the day, are proud to acknowledge themselves his pupils.

As an investigator he fully realised the promise of his early youth. His knowledge was as accurate as it was extensive, and that to a degree which only becomes comprehensible when we remember that unaided he contributed for nearly forty years a masterly summary of current researches into the natural history of the lower animals to the pages of the *Archiv für Naturgeschichte*. It is clearly impossible to give anything like a detailed account of such an active and many-sided career in a moderate space: let it suffice to recall his insistence on the division of labour in the animal kingdom, his researches on the reproduction of bees and of the Cephalopoda, his recognition of the ciliated organ of Heteropoda and Pteropoda as an osphradium, and his reference of *Neomenia* to the Mollusca.

Undoubtedly, however, his greatest energy was devoted to the study of parasitic life in general and to the life-history of the parasitic worms in particular. He at once recognised the importance of the methods of experimental helminthology introduced by Küchenmeister, and demonstrated the life-history of nearly all the bladder-worms then known by rearing them in suitable hosts. He was the author of epoch-making researches on *Trichina* and on the *Pentastomida*, and contemporaneously with the Englishman, A. P. Thomas, worked out the life-history of the Liverfluke. His work on the "Parasites of Man," the first volume of which has been translated into English, is a perfect cyclopædia of information derived from the writings of others and from his own observations. He has passed away full of years and full of honours, leaving a name which will ever be venerated by zoologists of every tongue and nation.

NOTES.

The first soirée of the Royal Society, to which gentlemen only are invited, is fixed for Wednesday, May 11.

On Saturday last (April 2) the Council of University College, London, elected Prof. H. L. Callendar, F.R.S., to the Quain Professorship of Physics, about to become vacant by the resignation of Prof. G. Carey Foster, who in a few months will have held his Professorship in University College for thirty-three years. Prof. Callendar, who has been Professor of Physics in McGill College, Montreal, will enter upon his duties in London in October next.

Sir William Turner, F.R.S., professor of anatomy in the University of Edinburgh, has been elected a corresponding member of the Berlin Academy of Sciences. He has also been elected president of the General Medical Council, in succession to the late Sir Richard Quain.

Prof. H. C. Bumpus has been appointed director of the laboratory of the United States Fish Commission Station at Wood's Holl.

Sir Samuel Wilks has been re-elected president of the Royal College of Physicians of London.

M. Richet has been elected a member of the Paris Academy of Medicine.

A "Jardin de Kew" is to be established in the neighbourhood of Nantes by a rich citizen of that town. The new botanical garden will be planned on the same lines as the Royal Gardens at Kew, and special attention will be given to the cultivation of plants useful in French colonies. It is hoped that the garden will eventually do for French colonial possessions what Kew does for British colonies.

The Paris correspondent of the *British Medical Journal* announces that a recent decree authorises the University of Paris to borrow 68,000*l.* for the purpose of building laboratories where physical science, chemistry, and natural history will be taught for the benefit of students who are preparing for the examination for Science Certificate. Part of the money is to be applied to the completion of the Laboratory of Vegetable Biology belonging to the University of Paris at Fontainebleau.

The policy exemplified by the following appointment, announced in *Science*, might be adopted with advantage in this country:—Dr. Charles Wardell Stiles, of the United States Department of Agriculture, has been appointed *attaché* to the United States Embassy in Berlin. Dr. Stiles's duty will be to keep the Agricultural Department informed on important discoveries and other matters of interest to agricultural science, to defend American meats, fruits and other exports against unjust discrimination, and to advise the Secretary of Agriculture from time to time concerning the purity of the food products that are shipped from Germany to the United States. It is said that the appointment of Dr. Stiles will probably be followed by other similar appointments, and it consequently represents an important advance in the application of scientific principles to diplomatic and commercial affairs.

A LETTER received a few days ago by Prof. Milne from Mr. H. Hamilton, Montserrat, West Indies, contains somewhat startling information. It appears that since the flood of November 29, 1896, which caused great injury to life and property in Montserrat, innumerable earthquake shocks have been experienced. There are several craters and sulphur springs in the island, and it is thought that the mouth of one of the numerous craters was filled up by a landslip caused by the flood referred to, for several shocks of earthquake—the first experienced for a great number of years—were felt on the night of the flood. It is suggested that the filling up of this crater has been the cause of all the earthquakes which have lately occurred in the island. But whatever may be the cause, there is no doubt that since November 1896, the island has been in a very disturbed seismological condition. Scarcely a day passes without a few shocks being felt, and as many as thirty distinct disturbances have often been experienced in one day. On February 15, 18 and 20 of this year, alarming shocks were felt; and it is affirmed that the worst shock on February 15 (11.16 a.m.) was just as severe as the great earthquake of 1843, but being of shorter duration it did not do so much damage. Several buildings have, however, been very badly damaged by the constantly-occurring disturbances, and innumerable cracks have appeared in nearly every stone building in the island. These earthquakes, says Mr. Hamilton, which have been continually felt since November 1896, are causing great anxiety among the inhabitants, and it is feared that the shocks will culminate in a volcanic eruption, or that the numerous stone buildings, weakened as they already are by the continual shocks, must in course of time be thrown to the ground unless the disturbances cease. The whole subject demands scientific inquiry, and it is to be hoped, both in the interests of science and of the people of Montserrat, that the Colonial Office, which has probably received official reports of the earthquakes, will send some one to the island to investigate them.

THE numerous cases of enteric fever which have been traced to the consumption of contaminated oysters, clearly points to the need of a change in the present condition of the law relating to the culture of oysters and other shell-fish. For the purpose of submitting a memorial in favour of an alteration of this law, a deputation from the corporations of twenty-five provincial towns, and the London County Council, waited upon the President of the Local Government Board a few days ago. As the law now stands, local authorities have no means of preventing the sale of shell-fish within their districts, even though they possess the clearest evidence that the consumption of the shell-fish has produced typhoid fever, and that the shell-fish is derived from a source known to be contaminated with sewage. In reply to the deputation, Mr. Chaplin said that he considered that the time had arrived for legislative action, and he had been engaged for some time on the measures necessary and appropriate to deal with the matter. As to the dangers which might arise from the sale of infected shell-fish other than oysters, he had not sufficient information to act upon, but with regard to oysters he hoped it would be possible for him soon to take action which would be satisfactory to the deputation.

A HOLIDAY course of science lectures and demonstrations will be held in Berlin from Wednesday, April 13, to Saturday, April 23. Lectures on most branches of science have been arranged, and visits will be made to museums and other places of scientific interest.

A MEETING of the Institution of Mechanical Engineers will be held on Wednesday and Friday, April 27 and 29. The chair will be taken by the President, Mr. Samuel W. Johnson, who will deliver his inaugural address at the opening meeting. The following papers will be read and discussed, as far as time permits:—"First Report to the Gas-Engine Research Committee: description of apparatus and methods, and preliminary results," by Prof. F. W. Burstall; "Steam Laundry Machinery," by Mr. Sidney Tebbutt.

ATTENTION has already been drawn in NATURE to the publication by the Geological Survey of a colour-printed map of the London area and great part of the Weald. This was Sheet 12 of the General Map on the scale of an inch to four miles. We are now able to state that all the fifteen sheets of this map have similarly been issued in the colour-printed form, at a uniform price of 2*s.* 6*d.*, with the exception of the title-sheet, the price of which is 2*s.* The total cost of the map, which if mounted would measure about 8 by 6 feet, is 1*l.* 17*s.*

A CORRESPONDENT from Bangor writes:—"An instance of a locally acquired habit in birds, on which it would be interesting to collect information from different districts, is afforded by the behaviour of sparrows towards the flowers of garden crocuses. Here in Bangor we have had crocuses blossoming two years in succession without a single flower being eaten off; in gardens at Cambridge, and other places, every flower is pulled to pieces almost before it has fully opened. It would seem that the flowers contain some agreeable flavouring matter which the Bangor birds have (fortunately) not yet learnt to appreciate."

MR. G. MARSHALL WOODROW, Professor of Botany at the Royal College of Science, Poona, went to Jeur at the time of the recent total solar eclipse, and made some botanical observations which he communicates to the *Gardener's Chronicle* (March 19). This station was not very suitable for luxurious vegetation, as the daily range of temperature during January was too great, the thermometer ranging from 45° F. to 145° F. and in the shade from 50° F. to 90° F. He, however, collected 130 species, including 26 Gramineæ, 27 Leguminosæ, 14 Compositæ, 9 Acanthaceæ, 5 Asclepiadaceæ, 5 Euphorbiaceæ, 5 Malvaceæ, 5 Cucurbitaceæ, 5 Convolvulaceæ, 2 Solanaceæ, 4 Labiatæ, 2 Urticaceæ, and 2 Capparidaceæ. Of the Gramineæ he mentions that the most frequent one, *Aristida setacea*, was in ripe seed, and it was interesting to observe its manner of distributing them. Its three-branched awns "twist together in such a manner that a perfect sphere is formed by their extended points, and the balls roll hither and thither in every breeze." Another grass of interest is the species Isachne, which has the habit of setting loose its entire inflorescence, a large open panicle of most elegant form, which is rolled about by the wind till it is caught in some bush. This species has an inflorescence larger than any other known; and since it was found while preparing to observe the eclipse, the name *Isachne obscurans* is proposed for it. Prof. Woodrow mentions that as the sunlight began to fade away, owing to the passage of the dark moon, Leguminosæ began to fold up their leaves, as is their manner at evening time.

MR. H. C. RUSSELL, Government Astronomer of New South Wales, has communicated a second paper to the Royal Society of that Colony, on the subject of icebergs in the Southern Ocean, from reports collected from masters of vessels trading to Sydney and from other sources. The first paper dealt with the icebergs in the South Atlantic which had been reported up to July 1895, and the present paper continues the discussion down to September 1897, during which time the great mass of the bergs has drifted from the South Atlantic to between longitude 40° and 80° in the South Indian Ocean, and have been subsequently reported south-eastward of New Zealand. It is somewhat remarkable that for months at a time very few icebergs were met with by vessels trading to Australia, and their motion into and out of the tracks of vessels made it seem probable that it was affected by the prevalent winds. A reference to the weather charts showed that when there was a prevalence of north-west wind no ice was reported, while with southerly winds bergs were frequently observed. Mr. Russell states that the records are too short to settle the question, but he is of opinion that by careful study of the winds in connection with the movements of the bergs it will be possible to forecast their positions from the winds prevailing in South Africa and Australia.

The Pilot Chart of the North Pacific Ocean for the month of March, published by the Hydrographer of the United States Navy, contains tables and charts giving the mean temperatures of the surface waters for each quarter and for the year for that part of the North Pacific Ocean comprised between latitude 30° and 60° N., and the west coast of North America and longitude 180° W. The material has been obtained from observations in the possession of the United States Hydrographic Office, supplemented by the data contained in the Russian Admiral Makaroff's work, "The *Vitiaz* and the Pacific Ocean." The coldest region is in 55°-60° N., and 155°-180° W., having for the months of May to September a mean temperature of 43°. In the same longitude, and latitude 50°-55° N., the mean annual temperature is 42°. The warmest region is in latitude 30°-35° N., longitude 140°-165° W., having a mean annual temperature of 68°. The yearly range of monthly temperature is highest in latitude 35°-40° N., longitude 150°-180° W., being 18°·5, and lowest 8°·5, in latitude 30°-35° N., longitude 115°-145° W.

The report of Mr. S. P. Langley, Secretary of the Smithsonian Institution, for the year ending June 30, 1897, has just reached this country. Following the custom of several years, Mr. Langley gives in the body of the report a general account of the affairs of the Institution and its bureaus—the U.S. National Museum, the Bureau of American Ethnology, the International Exchanges, the National Zoological Park, and the Astrophysical Observatory—while more detailed statements by the officers in direct charge of the various branches of the work are given in an appendix. We regret to see, in the report on the work of the National Museum, that the complete manuscript of an important and comprehensive work by the late Prof. Cope on the reptiles of North America, based on the museum collections, is withheld from the printer for want of funds for its publication, and at least four others, equally valuable and extensive, now in an advanced stage of preparation. Delay in the publication of these works will prove a hindrance to the progress of American natural history. The Bureau of American Ethnology has been very active. The field operations have been extended into a large number of states and territories, and incidentally into those districts of neighbouring countries occupied by native tribes closely affiliated with the aborigines of the territory now comprised in the United States. During the year covered by the report special attention was given to the classification of the tribes in such manner as to indicate their origin and development, and to this end the rich archives of the Bureau, comprising the accumulations of eighteen years of research, have been subjected to careful study, and important conclusions have been reached. The International Exchange Service continues to increase; and the fact that exchanges are now made with 28,000 correspondents in every part of the civilised world demonstrates, to some degree, the far-reaching influence of the Institution. The National Zoological Park has been improved by the construction of roads and a new bridge; but the buildings and enclosures of the Park are altogether inadequate, and there are no funds to supply the wants. Among the needs are suitable houses for the preservation and care of birds, a vivarium for small animals, and ponds for aquatic birds and mammals. The operations of the Astrophysical Observatory have consisted chiefly in experiments in the bolographic analysis of the infra red solar spectrum. The report upon this work has been completed; and it contains, in addition to introductory, historical, descriptive, and theoretical matter and accounts of subsidiary investigations, tables of positions of 222 absorption lines in the infra-red solar spectrum in terms of angular deviations and refractive indices for a rock-salt prism, and of the approximate wave-lengths corresponding. It is to be hoped that this report, containing results of great interest and value to physical science, will soon be published.

The election of Prof. James E. Keeler, director of the Allegheny Observatory, to the directorship of the Lick Observatory was announced in last week's Nature. We now learn that Prof. Keeler has written a letter to the Chairman of the Allegheny Observatory Committee stating that he is prepared to decline the call to the Lick Observatory if within two weeks 200,000 dollars can be collected for the erection of a new observatory with a thirty-inch telescope, and towards the endowment of a chair of astronomy in the Western University of Pennsylvania. Efforts are being made to obtain this sum of money, and as much as 137,000 dollars has already been subscribed, while Allegheny City has given a site for a new observatory in an elevated position surrounded by parks, and comparatively free from smoke. We wonder how many British cities and citizens would show in such a substantial way their anxiety to keep a distinguished scientific investigator within their borders.

An interesting observation upon the development of a taste for honey by starlings is recorded by Mr. W. W. Smith in the *Entomologist* (April). In a previous note referring to some enemies of humble-bees in New Zealand, Mr. Smith stated that he had observed the newly-introduced starlings killing and conveying humble-bees to their nests to feed their young. The tui or parson-bird (*Prosthemadera novæ-zealandiæ*) has now been detected killing them at Akaroa on Banks Peninsula. The case is remarkable in illustrating how new habits are acquired, or family habits are developed in some species of birds when certain conditions are present. As the tui belongs to the starling family, and is one of the native honey-suckers, it is possible it also was killing humble-bees to feed its young when it discovered the honey-sac of the insects. The tui, while engaged in killing the bees, would discover their honey-sac, which would also lead to a continuance of the habit as a ready means of procuring their favourite food. An analogous case is also presented in some recently acquired habits of the starling. For two seasons Mr. Smith has observed what is undoubtedly an acquired taste and habit in the starling in New Zealand. Like the tui, this bird now frequents the flax-flats and sucks the honey from the richly mellifluous flowers. It appears probable that the eating of the humble-bee's honey-sac by the starlings developed, or is now developing, the taste for honey in these birds.

From the many papers before us dealing with kathodic rays, Röntgen rays, and the closely-allied phenomena of "electro-dispersion," we extract the following:—Prof. Battelli and Dr. Garbasso (*Nuovo Cimento*, vi. 4) examined more closely the action of kathodic rays on insulated conductors, with the view of testing the existence of indeformable rays in the interior of the Crookes' tube. Their results agree with the hypothesis that the different modes of action of kathodic and Röntgen rays depend on the different conditions of the medium in which the conductor is placed.—M. P. de Heen (*Bulletin de l'Académie Royale de Belgique*, 1898, pp. 188, 191) publishes two papers relating to the electro-dispersive power of Röntgenised air, and also of air modified by a Bunsen burner. In the first paper the author obtains, by the Bunsen burner, results which cannot be accounted for on Villari's theory of Röntgenised air, but indicate the existence of a special kind of energy, to which he applies the name *infra-electric*. In the second paper he describes four experiments dealing with the propagation of what he calls *anti-electric* energy behind shadows. The papers leave us a little uncertain as to M. de Heen's distinction between the terms *infra-electric* and *anti-electric*; "anti"-electricity, we are told, includes both "infra"- and "ultra"-electricity, but the latter we do not see defined, at all events, in these two writings.

From Mr. A. A. Campbell Swinton we have received a reprint of his paper on adjustable X-ray tubes, read before the Röntgen Society.—Part iv. (vol. vii.) of the *Atti dei Lincei* contains two papers, one on the cryptoluminescence of metals, by Prof. A. Róiti; the other on the diffusion of Röntgen rays, by Drs. R. Malagoli and C. Bonacini. According to the two latter writers, (1) the two electrodes contemporaneously emit *ortho-kathodic* rays, but that which communicates with the negative pole of the excitor develops them the most intensely; (2) from the electrodes, at a certain stage of rarefaction, there seem to start two cones of radiation, one enclosed in the other or partially separate, carrying opposite charges; both are displaced by magnets subject to the same laws; (3) the violet anodic light, like the ortho-kathodic rays, is intensely affected by magnetic action, but it follows the opposite law, behaving like an electric current from the anode to the anti-anode; (4) it seems to follow that the anti-anodic system of Maltèzos is, perhaps, only a feeble anti-kathodic system, for between the two systems there is identity rather than mere analogy, and that not only in their effect on the glass.—The *Bulletin de la Société Française de Physique* (Nos. 108, 111) contains abstracts of two papers by M. Villard, the first dealing principally with the rays which produce the hemispherical illumination of "focus" tubes above the plane of the anti-kathode; the second dealing with the laws of variation of the resistance of a Crookes' tube, the electric attraction and repulsion of the seat of emission, the production of Goldstein's rays, and the nature of the kathodic rays. From their action in reducing crystals, silicates, oxides of copper, and other substances, M. Villard suggests that the kathodic rays are formed of molecules of hydrogen due to the traces of moisture left in the tube.—Dr. Josef R. v. Geitler, of Prague, contributes to the *Wiener Berichte* a paper on electric and magnetic decomposition of kathodic rays. The subject has been somewhat foreshadowed by Birkeland, and the investigation bears close analogy to one published by Prof. J. J. Thomson in October 1897. Like him the author, experimenting on the shadow of a wire placed in the kathodic pencil, has obtained a broadening out of the shadow, which appears bordered by a series of green fluorescent striæ separated by dark interspaces. Dr. Geitler claims, however, that his experiments are in many respects essentially distinct from Prof. Thomson's.

By the death recently reported from Allahabad of Sir Saiyid Ahmad Khan, Indian Moslems have lost a leader who devoted many years, with great success, to their educational welfare and to the extension of scientific knowledge. He may well be described as the apostle of education to the Mahomedans of India. His institute at Aligarh, with its own printing-press and journal, his Anglo-Oriental college at the same place, on the model of a college of Oxford or Cambridge, for the education of Mahomedans of the upper classes, are splendid monuments to his breadth of mind, his wisdom, and his energy. The following particulars of Sir Saiyid Ahmad's career are from an article in Wednesday's *Times*:—This great leader of his people and pillar of British rule, as he has been called, was born in Delhi in 1817. His ancestors, who claimed descent from the Prophet, are said to have originally come from the Herat Valley, and for several generations held high office in the Court of the Moghul Emperors of Delhi. In 1837, after his father's death, the young man entered the British service in the Court of the Judge at Delhi, and from that time until he finally retired from the service he remained in the judicial branch. It was immediately after the Mutiny also that he threw himself heart and soul into the cause of Mahomedan education, and one of his earliest steps was to establish a translation society which should prepare suitable books, the want of which he greatly felt. A few years later this useful association expanded into the Scientific Society of Aligarh, with its own press, from which translations of numerous works on history and various modern sciences have been issued for the use of Mahomedans. It was after a visit to England in 1870 that he bent his mind to the great undertaking of the Anglo-Oriental College at Aligarh, which was opened in 1873 by Sir William Muir, while the foundation-stone of the building now in existence was laid with much ceremony by Lord Lytton in 1877. Having retired from the service in 1876, Saiyid Ahmad was in 1878 appointed a member of the Viceroy's Council by Lord Lytton, the appointment being renewed for a further period by Lord Ripon. He has also been on the Legislative Council of the North-West Provinces. In 1888 he was made K.C.S.I. For many years past Sir Saiyid Ahmad's home at Aligarh has been the goal of the pilgrimages of many of the greatest personages in India, and his reception by his fellow-Mahomedans when he has gone to the Punjab or to Haidarabad has been semi-regal. His last years were wholly devoted to the prosperity of his college and institute, and most of his journeys have been made on their behalf. Anglo-Indians who knew him best are as enthusiastic in his praise as the Indian Mahomedans. To the end he never changed the main article of his social faith—that education was the one indispensable requirement of Indian Mahomedans if they were to maintain under the British Raj the high position which was their due.

An interesting address, by Prof. Thomas Gray, on the development of electrical science, in which the history of electrical progress since the beginning of the seventeenth century is traced, is published in *Science* of March 18 and 25.

Herr Freiherr v. Richthofen, President of the Berlin *Gesellschaft für Erdkünde*, contributes a note to the *Verhandlungen* on the spelling of Chinese names. With the ordinary German pronunciation, *Kiautschou* represents the Chinese name more correctly than *Kiaotschau*, *Tschifu* than *Chefoo*, *Niutschwang* than *Newchwang*, *Futschoufu* than *Foochowfoo*.

The whole of the first number of the new volume of the *Mittheilungen von Forschungsreisenden und Gelehrten aus den deutschen Schutzgebieten* is taken up with an exhaustive account of the drum language of the Duala, by Herr R. Betz. This method of conversation at a distance reaches a higher development in the Duala region than in any other part of the Kameruns. The paper contains no fewer than 275 examples of signs and phrases.

From an advance proof of the tables relating to the output of coal and other minerals in 1897, published by the Home Office, we learn that 202,119,196 tons of coal were mined in the United Kingdom last year. This was an excess of nearly seven million tons over the output for 1896. Next to coal, the largest outputs were:—ironstone, 7,793,168 tons; fireclay, 2,682,472 tons; oil shale, 2,223,757 tons.

Prof. Dr. J. Walther contributes a further instalment of his studies of deserts to the *Verhandlungen* of the *Gesellschaft für Erdkünde zu Berlin*. Prof. Walther made an expedition into the waste regions of Transcaspia and Bokhara after the Geological Congress at St. Petersburg last year, and describes his observations on the erosive action of wind, of great ranges of temperature, and of the saline deposits in dried-up lakes. The paper forms an important addition to the author's geological work in similar regions of North America and North Africa.

The "Statesman's Year-Book," edited by Dr. J. Scott Keltie, with the assistance of Mr. I. P. A. Renwick, annually improves in character and increases in usefulness. The volume just published by Messrs. Macmillan and Co. is the thirty-fifth; and it contains in the 1166 pages the latest statistical and other data referring to all the States of the world. The special features this year are maps showing, by means of different colours, the distribution of British commerce throughout the world, a map illustrating the Niger question, and a series of coloured diagrams exhibiting the course of trade in leading countries during the past twenty-five years. Trustworthy information upon all questions of political and commercial geography can be obtained from the volume, which keeps its place as the most handy and complete annual of geographical statistics in existence.

The additions to the Zoological Society's Gardens during the past week include a Molucca Deer (*Cervus moluccensis*, ♂) from the Molucca Islands, presented by H.G. the Duke of Bedford; a Great-billed Touracou (*Turacus macrorhynchus*) from West Africa, presented by Mr. R. J. Nicholas; two Cambayan Turtle Doves (*Turtur senegalensis*) from West Africa, presented by Sir Edward Burne-Jones; a Macaque Monkey (*Macacus cynomolgus*) from India, presented by Captain Francis W. Bate; two Arctic Foxes (*Canis lagopus*) from the Arctic Regions, four Oyster-catchers (*Hæmatopus ostralegus*), European, purchased; a Caucasian Wild Goat (*Capra caucasica*, ♂, juv.) from the Caucasus, received in exchange; a Burchell's Zebra (*Equus burchelli*, ♀), born in the Gardens.

OUR ASTRONOMICAL COLUMN.

Spectrum Analysis of Meteorites.—A research of great interest has been undertaken by Messrs. W. N. Hartley and Hugh Ramage on the wide dissemination of the rarer elements and the mode of their association in the more common ores and minerals. The outcome of this work has led us to believe that the rarer metals are more widely distributed than was ever dreamt of, the authors showing that out of ninety-one iron ores obtained from the Dublin Royal College of Science, thirty-five contained the extremely rare metal gallium, while most of them contained constituents of an unusual character. Thus rubidium was commonly present: the magnetites invariably contained gallium, but no indium; the siderites all contained indium, but lacked gallium. In a more recent research they have investigated spectroscopically numerous meteoric ores, siderolites and meteorites (*Scientific Proc. of the R. Dublin Soc.*, vol. viii. (N.S.) Part vi., No. 68), the range of spectrum being between the wave-lengths 6000 and 3200, and the results they obtained in this case, arranged in tabular form, are of great interest. It is shown that the composition of different meteoric irons is very similar, though the proportions of constituents differ somewhat. Meteoric irons, different varieties of iron ores, and manufactured irons contain copper, lead, and silver. Gallium is a constituent of meteoric irons, but not of all meteorites, and occurs in varying proportions. Sodium potassium and rubidium are constituents of meteoric irons, but only in very small proportions. Meteoric stones, but not the irons, contain chromium and manganese. Nickel was found to be a principal constituent in all meteorites, meteoric irons, and siderolites, cobalt occurring in the two last varieties. The authors describe the chief points of difference between telluric and meteoric iron to be the absence of nickel and cobalt in any considerable proportion from the former, and the presence of manganese. Meteoric irons, on the other hand, contain nickel and cobalt as notable constituents, and, except in minute traces, manganese is absent. In referring to the photographic spectra of iron meteorites obtained by Sir Norman Lockyer from the Nejed and Obernkirchen meteorites, the authors point out that of the two lines, one described as "unknown," and the other as "doubtfully ascribed to iron," the former is certainly, and the latter probably, a gallium line. At the conclusion of their paper the authors give three plates, which reproduce the flame spectra of six metallic irons and three siderolites with comparison spectra.

Stellar Parallaxes.—Dr. Bruno Peter, during the years 1887 to 1892, made a series of parallax observations with the Leipzig heliometer. The results of this investigation have been published in vol. xxii. No. 4, and xxiv. No. 3, of the *Abhandlungen der Math.-Phys. Classe der K.S. Gesel. der Wissenschaften*; but Dr. Peter makes a short abstract in the *Astronomische Nachrichten*, No. 3483, which we briefly refer to here. In the following table, which brings together these results very clearly, ε represents the mean error of the parallax, and ε' that for one evening. In the three references to the star Lal 18115, (1) relates to the preceding component, and (2) to the following one, while (3) deals with the pair as a whole. The last column gives the comparison stars employed in each case.

JAMES WATT, AND THE DISCOVERY OF THE COMPOSITION OF WATER.[1]

When your Secretary did me the honour to communicate the wish of the Committee that I should deliver this lecture, he was good enough to send me a list of the names of my predecessors in the position I was invited to occupy, together with a statement of the subjects on which they had addressed you. I confess I read his letter with very mingled feelings. To be asked to form one of such a distinguished company was in itself an honour which I deeply appreciated. On the other hand, it seemed well-nigh hopeless to find any theme associated with the life and work of the great man whose services to humanity we are this day called upon to commemorate, that had not been dealt with by one or other of those who preceded me. Naturally, and as befits the subject, the greater number of those who have spoken on these occasions have been distinguished engineers and mechanicians, and they have been able to speak with a fulness of knowledge, and a weight of authority, on the outcome of the great engineer's labours to which I, who know nothing of engineering or machinery, can have no pretensions.

It occurred to me, however, on reflection, that there was one incident in Watt's career, which, so far as I could learn, had not been handled by any one of those whom you have invited to appear here, and to which, as it comes within my own province, I thought I might venture, without presumption, to engage your attention. I was the more impelled to select it in that it illustrates one side of Watt's intellectual activity which those who regard him only as an inventor and a mechanician are apt to undervalue or lose sight of altogether. It serves, too, to throw additional light upon his mental character and moral worth, and thus enables us to form a fuller and more just appreciation of the attributes of the man we wish to honour. The incident, in a word, relates to Watt's share in the establishment of the true view of the chemical nature of water.

To the historian of science this is doubtless an old story, on which it would be difficult to say anything new. The literature concerned with it occupies many volumes, largely owing to the circumstance that it has given rise to a controversy which has engaged the active interest of some of the strongest and subtlest intellects of this century. Some of the disputants have been men like Brougham, Jeffrey and Muirhead, skilled in the arts of advocacy and in the faculty of eliciting and weighing evidence, who have stated their conclusions with all the "pomp and circumstance" of a judicial finding; others are men like Arago, Dumas, Harcourt, Whewell, Peacock, Kopp, George Wilson, eminent in science and literature. who have defended their convictions with great power, ample knowledge, much argumentative force, and occasional eloquence. At one time the contest was waged with no little fury and bitterness; it threatened, indeed, like the famous controversy on the proper form of a lightning-conductor during Sir John Pringle's presidency of the Royal Society, or like the equally famous controversy on the discovery of the planet Neptune, to attain the dignity of a national question, far more acute, I should imagine, than that which has just occasioned all right feeling Scotchmen to approach the Queen in Council on the subject of Scotland's proper place and designation in Imperial concerns.

---

[1] The Watt Memorial Lecture, delivered in the Watt Memorial Hall, Greenock, on March 11, by Prof. T. E. Thorpe, LL.D., F.R.S.

But the acrimony and ill-feeling have happily long since passed away. There is no longer any need to discuss the question either as an advocate or as a partisan. What I shall attempt to-night is to treat it dispassionately, and, within the compass of an hour, to assess, as impartially as I am able, Watt's true place in regard to this discovery.

It was, indeed, an epoch-making event. The discovery of the composition of water was as momentous for science as the greatest of Watt's inventions was for social and economic progress. The very fact itself, apart from all that flowed from it, was of transcendent interest. But to those who had eyes to see, its supreme importance was in its fruitful and far-reaching consequences. It signified nothing less than the passing away of an old order of things, the downfall of a system of philosophy which had outlived its usefulness, in that it no longer served to interpret natural phenomena, but which was rather a hindrance and a stumbling-block to the perception of truth. The discovery at once led to the inception of a more rational and more truly comprehensive theory, which not only explained what was already known, in a fuller, clearer and more intelligible manner, but pointed the way to new facts hitherto undreamt of, which, in their turn, served to strengthen and extend the generalisation which led to their discovery. No wonder, then, that those who loved and revered Watt, and who were rightly jealous of his honour, should have sought to do all in their power to vindicate what they honestly conceived to be his just title to so signal and so fundamental a discovery.

No man has a juster claim to be regarded as a scientific man, in the truest and noblest sense of that term, than James Watt. The scientific spirit was manifest in him even in boyhood. The very circumstances of his condition, his weakly frame, the solitariness of his school-life, and the early habits of introspection thus induced in a mind forced to feed only on itself, served to strengthen and develop the instinct. Even his early struggles, and the jealousy of the Glasgow Guilds which forbade him to practise his trade in the burgh in which he had not served an apprenticeship, conduced to mould his character and to determine the bent of his mind. Hard and illiberal as it seemed at the time, the *Zunftgeist* which drove him to the shelter of the old College in the High Street, and secured for him the abiding friendship of Black and Robison, was in reality the most fortunate circumstance in his career. It brought him directly under the influence of one of the greatest natural philosophers of his age, and so stamped him permanently as a man of science. It would not be difficult to trace how this influence reacted upon all that Watt subsequently did—from the time of his earliest speculations on the loss of energy in Newcomen's engine down to the very last of his mechanical pursuits in the dignified retirement of Heathfield Hall. He approached the question of the improvement of the steam-engine as a scientific problem, and under the direct inspiration of the doctrine of the great discoverer of the principle of latent heat. It was this same mental attitude towards scientific truth, the same receptivity for scientific doctrine, the same love of pondering over and speculating upon the true inwardness of things that brought him the friendship of Priestley, Withering, Wedgwood and De Luc, and that ultimately made him a cherished member of the foremost scientific academies of the world. It will occasion little surprise to one who has formed a true perception of his character to learn that Watt was wont, even at periods of great mental depression, and of physical suffering, amidst all the toil and anxious worry of a business surrounded with difficulties, to find peace in the contemplation of natural phenomena, and to spend time in philosophical speculation. The shrinking, diffident man, in thus communing with himself and with nature, followed a true and constant impulse to withdraw from the strife and turmoil of the world, and to seek his pleasure and his rest in the silent contemplation of natural truth. No one can look upon that contemplative face without being struck with its expression of philosophic calm. What deep, genuine pleasure these communings brought to the harassed man may be gleaned from his correspondence. In truth, nature intended Watt to be a philosopher of the pattern of Boyle, or Newton, or Dalton; it was destiny that drove him into the world of affairs where, as he said, he was out of his sphere. It is necessary to dwell for a moment on this aspect of Watt, in order to form a just appreciation both of his position and of his merits in regard to the great chemical truth with which his name is associated.

The man of action is apt to regard the contemplative mind with something akin to contempt. I once heard a bustling, busy man, the head of a large engineering establishment, who had enjoyed the good fortune to be a pupil of Thomas Graham, say of that distinguished philosopher that he was the laziest man he had ever met. He did not say he "ever knew"—for how little he really knew of Graham was evident from the fact that at the period to which he referred Graham's thoughts were deeply occupied with some of the most memorable of his investigations.

It was in one of these contemplative moods—in what he himself styled his periods of excessive indolence—and as it happened at the very time that the Soho firm was struggling to protect itself against the unprincipled horde that was seeking to infringe Watt's fundamental patent, that he occupied himself with turning over in his mind the outcome of one of his friend Priestley's multitudinous experiments. Watt had long held the view that air was a modification of water, or, as he expressed it in a letter to his friend Black, under date December 13, 1782, that, "as steam parts with its latent heat as it acquires sensible heat, when it arrives at a certain point it will have no latent heat, and may, under proper compression, be an elastic fluid nearly as specifically heavy as water": at which point he conceived it would again change its state and become air. As he then relates, he sees a confirmation of this opinion in an experiment of Priestley's made, as he says, "in his usual way of groping about." "As he [Priestley] had succeeded in turning the acids into air by heat only, he wanted to try what water would become in like circumstances. He undersaturated some very caustic lime with an ounce of water, and subjected it to a white heat in an earthen retort. . . . No water or moisture came over, but a quantity of air, equal in weight to the water . . . a very small part of which was fixed air, and the rest of the nature of atmospheric air. . . . He has repeated the experiment with the same result."

About a fortnight later Priestley wrote that he was able to convert water into air "without combining it with lime or anything else, with less than a boiling heat, in the greatest quantity, and with the least possible trouble or expense." He added that "the method will surprise more than the effect," but that he would defer "the communication of the hocus pocus of it" until such time as Watt should give him the pleasure of his company in return for the pleasure he was to give Watt in speculating on the subject.

These experiments, as we shall see in due course, were wholly fallacious; in following them up with his wonted ardour, Priestley quickly found himself in a maze of contradictions, and ultimately discovered that this seeming conversion was absolutely mythical.

It may be useful, however, to make one or two comments on these passages at the present juncture. In the first place Watt's opinion as to the relation of water and air, although founded, as he thought, upon a more philosophical basis, simply embodied the teaching of the schoolmen. The notion that the so-called four elements were mutually convertible, or were in essence identical, ran through the doctrine of twenty centuries of teachers. Despite the onslaughts of the Spagyrists, and the author of the "Sceptical Chymist," it permeated the literature of natural philosophy down to the very beginning of this epoch. Watt was insensibly swayed by a belief which had descended to him, like the undying germ, through the ages, and he could no more shake himself free of it than he could get rid of the influence of heredity. The very mode in which he, in common with men of his time, uses the term "air," is an indication of the manner in which the ancient creed limited and cramped his thought. He knew that there were various "airs," but it is very doubtful if he realised that they were essentially different substances. There is abundant evidence in the few chemical papers that he published, and especially in his letters to Black, Priestley, De Luc, Kirwan and others, that he regarded them all as constituted of the same matter, affected by attributes more or less fortuitous and accidental. Thus, all the varieties of inflammable air were at bottom identical, with properties modified by their origin or their varying content of the hypothetical principle phlogiston—that is the principle that was assumed to make them burn.

From Watt's published correspondence we are able to judge how he regarded Priestley's further work on this so-called conversion of water into air. He admits that the facts are "in some degree contradictory to each other." The apparent conversion would seem to depend upon the material of the vessel in which it was made. In a glass vessel no air was produced, nor was any found in a gun-barrel when the distillation was done slowly; but when confined by a cock, "and let out by puffs, it produces much air; which," says Watt, "agrees with my theory, and also coincides with what I have observed in steam-engines. In some cases I have seen the tenth of the bulk of the water, of air extricated or made from it." Davy once said "the human mind is governed not by what it knows, but by what it believes; not by what it is capable of attaining, but by what it desires." However willing to catch at anything in support of his belief, it is possible that Watt might have been led to doubt the soundness of Priestley's experiment, if an apparent and wholly unlooked for confirmation of it had not arisen.

To make the account exact, and in view of what is to follow, it is necessary to go back a little, in point of time. In the spring of 1781, Priestley performed what he styled "a mere random experiment made to entertain a few philosophical friends." It was practically a repetition of Volta's experiment of firing a mixture of the inflammable air from metals, that is, hydrogen, with common air in a closed glass vessel by means of the electric spark. After the deflagration the vessel was found to be hot, and on cooling its sides were observed to be bedewed. Neither Priestley nor any of his philosophical friends seem to have paid particular attention to the deposit of moisture, or, at all events, if they did they failed to perceive its significance. One of them, however, Mr. John Warltire, a lecturer in natural philosophy in Birmingham, imagined that the experiment might afford the means of showing whether heat was ponderable or not; and accordingly he repeated it, using for greater safety a copper globe, weighed before and after the passage of the spark. A minute loss of weight was always noticed, "but not constantly the same; upon the average it was about 2 grains."[1]

Priestley, who, with Withering, was present when the experiments were made, confirmed the apparent loss of weight; but he added, with a caution that was not characteristic, that he did not think "that so very bold an opinion as that of the latent heat of bodies contributing to their weight should be received without more experiments, and made upon a still larger scale."

Priestley's volume—the sixth in the series—was published in 1781, and was certainly known to Watt; indeed, in the Appendix are printed a number of observations made by him apparently as the work was passing through the press. Although, therefore, he must have had his attention drawn about this time to the formation of the dew in Priestley and Warltire's experiment, there is nothing to show that he attached any importance to the circumstance, or that, if he did, he dissented from Warltire's conclusion that common air deposits its moisture when it is phlogisticated.

For some time previous to the publication of Priestley's book, Mr. Cavendish was engaged upon an inquiry "to find out the cause of the diminution which common air is well known to suffer by all the various ways in which it is phlogisticated, and to discover what becomes of the air thus lost or condensed." In other words, it was an investigation to determine the changes experienced by air when bodies were made to burn in confined portions of it. On the appearance of Priestley's book he repeated Warltire's experiment, thinking "it worth while to examine more closely, as it seemed likely to throw great light on the subject I had in view." He confirmed the observation on the formation of dew; but although he made the experiment on a larger scale, and with varying proportions of the two airs, he was unable to satisfy himself as to the loss of weight after the explosion. As the result of a number of trials, made both with the inflammable air from zinc and from iron—that is, hydrogen—and mixed with common air in the proportion of 423 measures of the inflammable air to 1000 of common air, he says, "we may safely conclude that when they are mixed in this proportion, and exploded, almost all the inflammable air and about one-fifth part of the common air lose their elasticity, and are condensed into the dew which lines the glass." In order to examine the nature of this dew, large quantities of the hydrogen were burnt with two and a half times its volume of common air, and the product of the combustion was caused to pass through a long glass tube whereby it was condensed. "By this means 135 grains of water were condensed in the cylinder [*i.e.* the tube], which had no taste nor smell, and which left no sensible sediment when evaporated to dryness; neither did it leave any pungent smell during the evaporation; in short, it seemed pure water. . . . By the experiments with the globe, it appeared that when the inflammable and common air are exploded in a proper proportion, almost all the inflammable air and nearly one-fifth of the common air, lose their elasticity, and are condensed into dew. And by this experiment it appears that this dew is plain water, and consequently that almost all the inflammable air and about one-fifth of the common air are turned into pure water."

The idea that common air was for the most part a mixture of two gases—oxygen or the dephlogisticated air of Scheele and Priestley, and nitrogen or the mephitic air of Rutherford, the azote of Lavoisier—was familiar to chemists at this period as the result of the teaching of Scheele and Lavoisier, and there is reason to suppose that this opinion was shared by Cavendish. He had been engaged for some time past in an elaborate inquiry into the constitution of atmospheric air, the results of which admitted of no other interpretation than that common air was composed of two different gases, mixed or combined in constant relative proportions. It is true that in the memoir containing the results of his inquiry he nowhere directly gives his estimate of these relative quantities, but, from the data he affords, it is easy to deduce the amount and the constancy of the proportion. Cavendish's papers are characterised by remarkable conciseness and brevity; an experiment which must have involved the putting together of elaborate and complicated apparatus, and which must have occupied considerable time in its performance, is described in a few lines, and hence it is not always possible to gather with certainty the precise disposition of the arrangements. He never sets out his reasons or his conclusions with any great amount of detail, and his published words occasionally give little indication of his line of thought. But that he clearly recognised that only one portion of common air was concerned in the formation of water, and that this portion was the dephlogisticated air, or oxygen, is obvious from the next series of experiments in which he fired a mixture of about two measures of hydrogen and one measure of oxygen in a previously exhausted glass globe furnished with an apparatus for firing air by electricity. When the included air was fired, almost all of it lost its elasticity, so that fresh quantities of the explosive mixture could be introduced and the process repeated until a sufficient quantity of the moisture was obtained for examination. In these experiments Cavendish clearly and definitely demonstrated that the weight of the water was practically equal to the weight of the mixed gases which had combined to form it. In some cases the water was perfectly neutral in its reaction; in others it was slightly acid, and the cause of this acidity caused Cavendish much experimenting, but he is never in any doubt as to the main result; he says distinctly, "if those airs could be obtained perfectly pure, the whole would be condensed." Now if Cavendish had published this main result at the time he obtained it, namely in the summer of 1781, or even if he had formally communicated it to one of the meetings of the Royal Society during the ensuing session, there would have been no Water Controversy. But even if he were ready, it was characteristic of him to delay, not from inertia or indolence, but from a morbid shyness, an unconquerable reticence, which constantly led him to postpone any public announcement of his work. He had the additional, and to him all-sufficient, reason that he had not yet worked out the cause of the occasional acidity of the water. What he did, however, was to communicate the facts of his experiments to Priestley, as Priestley himself states in a subsequent paper published in the *Philosophical Transactions* for 1783. When or how he communicated them to Priestley does not appear, nor have we any means of knowing precisely what was said. Something, however, on this point may be inferred from what

---

[1] The account of these experiments is given in a letter to Priestley, and constitutes No. v. of the "Appendix to Priestley's Experiments and Observations relating to various branches of Natural Philosophy, &c.," vol. ii. (Birmingham, 1781).

Priestley proceeded to do. It appears from a letter to Wedgwood that he repeated Cavendish's experiment during the March of 1783. It will be remembered that he was at this period engaged on his experiments on the seeming conversion of water into air. He had obtained a number of contradictory results which had led Wedgwood, as far back as the previous January, to put certain sagacious queries, which doubtless in the end had their effect in opening Priestley's eyes to the origin of his mistake. But at the time both he and Watt were seeking for fresh evidence to substantiate the possibility of this conversion. Now just as Cavendish thought that Warltire's experiment might throw light upon the particular matter on which he was engaged, so Priestley considered that Cavendish's work might afford evidence, indirect it is true, but still evidence, of the intimate connection between water and air. Cavendish had, he thought, established the converse of the proposition which he and Watt were seeking to prove in showing that "air," or rather certain kinds of "air," could be converted into water weight for weight. It was no longer the original Warltire experiment of exploding common air and hydrogen. Cavendish had indicated the particular kinds which were really concerned in the phenomena, and it was the Cavendish experiment, pure and simple, which he proceeded to repeat. This is obvious from what he says: "Still hearing of many objections to the conversion of water into air, I now gave particular attention to an experiment of Mr. Cavendish's concerning the *reconversion* of air into water by *decomposing* it in conjunction with inflammable air." Priestley here used the word "decomposing" in a sense contrary to that which the context implies; but that he is consistent in so using it is evident from what follows, and also from similar expressions to be found in his correspondence. But although he professed to repeat Cavendish's experiment, he neglected to do so in Cavendish's manner. He says: "In order to be sure that the water I might *find in the air was really a constituent part of it*, and not what it might have imbibed after its formation [*i.e.* by contact with the water of the pneumatic trough], I made a quantity of both dephlogisticated and inflammable air, in such a manner as that neither of them should ever come into contact with water, receiving them as they were produced in mercury; the former from nitre, and in the middle of the process (long after the water of crystallisation was come over), and the latter from perfectly made charcoal. The two kinds of air thus produced I decomposed by firing them together by the electric explosion, and found a manifest deposition of water, and to appearance in the same quantity as if both the kinds of air had been previously confined by water.

"In order to judge more accurately of the quantity of water so deposited, and to compare it with the weight of the air decomposed, I carefully weighed a piece of filtering-paper, and then having wiped with it all the inside of the glass vessel in which the air had been decomposed, weighed it again, and I always found, as nearly as I could judge, the weight of the decomposed air in the moisture acquired by the paper. . . . I wished, however, to have had a nicer balance for the purpose: the result was such as to afford a strong presumption that the air was reconverted into water, *and therefore that the origin of it had been water.*"

These passages, when compared with the accounts given of his own work by Cavendish, strikingly exemplify the difference in the character of the two experimentalists. It would be difficult to pack a greater number of errors into a couple of paragraphs than are contained in these sentences. The expressions in italics show that Priestley wholly failed to comprehend the true origin of the water. In his laudable anxiety to free the two gases from extraneous moisture, he committed blunder after blunder. His method of obtaining the oxygen was bad; that of procuring the inflammable air was worse. Both the gases must have been highly impure, and it was a physical impossibility that they should have given their aggregate weight in water, even after making every allowance for Priestley's crude and imperfect method of determining it.

Bad, however, as the experimental work was, what it appeared to teach was not lost on Watt: it clearly proved to him that water and air were mutually convertible. How the theory took shape in his mind is evident from the terms in which the two series of Priestley's experiments are coupled together in his letters to Gilbert Hamilton, to De Luc and to Black. Each set is regarded as complementary to the other, and, both taken together, are held to prove that air and water are mutually convertible, and are therefore essentially the same. Under date April 21, 1783, he tells Black that "Dr. Priestley has made more experiments on the conversion of water into air, and I believe I have found out the cause of it; which I have put in the form of a letter to him, which will be read at the Royal Society with his paper on the subject." He then proceeds to give Black a summary of the three sets of facts, or supposed facts, on which he bases his generalisation, and he makes use of these significant words: "In the deflagration of the inflammable and dephlogisticated airs, the airs unite with violence—become red-hot—and on cooling, totally disappear. The only fixed matter which remains is *water*; and *water*, *light* and *heat* are all the products. Are we not, then, authorised to conclude that water is composed of dephlogisticated and inflammable air, or phlogiston, deprived of part of their latent heat, and that dephlogisticated, or pure air, is composed of air deprived of its phlogiston, and united to heat and light; and if light be only a modification of heat or a component part of phlogiston, then pure air consists of water deprived of its phlogiston and its latent heat." Very similar turns of expression and trains of reasoning are to be met with in other letters to his friends, written at about the same period. In all it is abundantly clear that, whatever may have been his surmises as to the real nature of water, it was the conception of the mutual convertibility of air and water that was uppermost in his mind. These passages, however, constitute Watt's claim to be regarded as the true and first discoverer of the compound nature of water.

Three days after the letter to the Royal Society was written, or rather dated, there came a bolt from the blue in the form of a letter from Priestley to Watt. "Behold," it said, "with surprise and with indignation the figure of an apparatus that has utterly ruined your beautiful hypothesis, and has rendered some weeks of my labour in working, thinking, and writing almost useless." The doubts of Wedgwood, certainly no mean authority on the properties of baked clay, had, in fact, led Priestley to devise an experiment by which it was proved beyond all doubt that this seeming conversion of water into air was really due to an interchange of steam and air, effected by diffusion through the porous material of the retort. Well might Priestley cry to De Luc, "We are undone!" Watt's faith in the "beautiful hypothesis" was no doubt rudely shaken, but it was not shattered. In his answer to Priestley he denied that it was ruined: "It is not founded," said he, "on so brittle a basis as an earthen retort." Priestley, however, would have none of it: theories with him—always excepting the all-comprehensive one of phlogiston, which was the head and front of his creed, as, indeed, of his subsequent offending—had at no time much value, for, as Marat said of Lavoisier, he abandoned them as readily as he adopted them, changing his systems as he did his shoes. Indeed, he rather prided himself on his capacity for quick change. "We are, at all ages," he once said, "but too much in haste to *understand*, as we think, the appearances that present themselves to us. If we could content ourselves with the bare knowledge of new facts, and suspend our judgment with respect to their causes, till by their analogy we were led to the discovery of more facts, of a similar nature, we should be in a much surer way to the attainment of real knowledge." With a candour all his own, he immediately added: "I do not pretend to be perfectly innocent in this respect myself; but I think I have as little to reproach myself with on this head as most of my brethren; and whenever I have drawn general conclusions too soon, I have been very ready to abandon them. . . . I have also repeatedly cautioned my readers, and I cannot too much inculcate the caution, that they are to consider new *facts* only as discoveries, and mere *deductions* from these facts, as of no kind of authority; but to draw all conclusions, and form all hypotheses, for themselves."

Watt's mind was of a very different cast. He did not lightly adopt opinions; his convictions were slowly and deliberately formed, and were retained with a corresponding tenacity. But, all the same, he eventually thought it prudent to withdraw his letter; and three days prior to the reading of Priestley's paper, which accompanied it, Priestley informed Sir Joseph Banks of Watt's desire that the letter should not be publicly read. That it was withdrawn on account of what Watt calls Priestley's "ugly experiment," is stated by him in a letter to Black, on the ground that this experiment rendered "the theory useless in so far as relates to the change of water into air. . . . I have not given up my theory [that is, as to the mutual convertibility of water into air], though neither it nor any other known one will account for this experiment."

In the meantime Cavendish had been pursuing his inquiries, and towards the end of this year (1783) he was prepared to give the explanation of the cause of the disturbing factor in his proof of the real nature of water—that is, the origin of the occasional and apparently haphazard presence of small quantities of nitric acid. This he demonstrated to be due to the difficulty of excluding a greater or less quantity of atmospheric nitrogen from the gases employed; and he determined the conditions under which this nitrogen led to the formation of the acid, the true nature of which he thus for the first time established. The account of his labours was read to the Royal Society on January 15, 1784.

In the previous autumn, however, disquieting rumours reached this country that the French philosophers, and chief among them Lavoisier, were poaching upon the English preserves. The circumstance is alluded to in a letter from Watt to De Luc, dated November 30, 1783. "I was at Dr. Priestley's last night. He thinks, as I do, that Mr. Lavoisier, having heard some imperfect account of the paper I wrote in the spring, has run away with the idea and made up a memoir hastily, without any satisfactory proofs. . . . I, therefore, put the query to you of the propriety of sending my letter to pass through their hands to be printed; for even if this theory is Mr. Lavoisier's own, I am vain enough to think that he may get some hints from my letter, which may enable him to make experiments, and to improve his theory, and produce a memoir to the Academy before my letter can be printed, which may be so much superior as to eclipse my poor performance and sink it into utter oblivion; nay, worse, I may be condemned as a plagiary, for I certainly cannot be heard in opposition to an Academician and a financier. . . . But, after all, I may be doing Mr. Lavoisier injustice."

That Lavoisier did get some hints, and possibly even through the medium of Watt's letter, is beyond all question. The fact that he was informed of Cavendish's work is specifically stated in Cavendish's memoir in a passage interpolated by Blagden, the Secretary of the Royal Society and Cavendish's assistant and amanuensis, who himself told Lavoisier. The whole of the circumstances are set out in detail in a subsequent letter which Blagden addressed to the editor of the *Chemische Annalen* in 1786. That it was known to be Cavendish's experiment that was being thus repeated, is confirmed by a letter from La Place to De Luc, dated June 28, 1783, in which we read: "Nous avons répété, ces jours derniers Mr. Lavoisier et moi, devant Mr. Blagden, et plusieurs autres personnes, l'expérience de Mr. Cavendish sur la conversion en eau des airs dephlogistiqués et inflammables, par leur combustion. . . . Nous avons obtenu de cette manière plus de 2½ gros d'eau pure, ou au monis qui n'avoit aucun caractère d'acidité, et qui étoit insipide au goût; mais nous ne savons pas encore si cette quantité d'eau représente le poids des airs consumes; c'est une expérience à recommencer avec toutes l'attention possible et qui me paroit de la plus grande importance." The phrase "qui n'avoit aucun caractère d'acidité" is of special significance. The French philosophers, and Lavoisier in particular, could with difficulty, as Blagden relates, be brought to credit the statement that when inflammable air was burnt, water only was formed; their preconceptions concerning the part played by oxygen in such a case, led them to suppose that an acid would be produced. Cavendish was familiar with Lavoisier's doctrine, which is connoted in the very word oxygen, which we owe to the French chemists; and it may be that this circumstance was, amongst others, one cause of the pains he took to understand the origin of the acid he occasionally met with. Lavoisier was led to repeat Cavendish's experiment on June 24, 1783; and on the following day he announced to the Academy that by the combustion of inflammable air with oxygen "very pure water" was formed. It is this statement that has been said to constitute Lavoisier's claim to be considered as the true and first discoverer of the composition of water. That he has no valid claim has been implicitly admitted by Lavoisier himself. The eminent Perpetual Secretary of the French Academy, M. Berthelot, is no doubt accurate in regarding June 25, 1783, as the first certain date of publication of the discovery that can be established by authentic, *i.e.* official, documents; but, as I have elsewhere attempted to show, the circumstances under which that priority of publication was secured give Lavoisier no moral right to the title of the discoverer.[1]

Shortly after the reading of Cavendish's memoir to the Royal Society (January 15, 1784), De Luc wrote to Watt, giving an account of its contents, and insinuating that its conclusions had been formed in the light of knowledge obtained from Watt's letter to the Royal Society, which although, as we have seen, not publicly read, had, there is no doubt, been perused by others than Priestley, to whom it was originally addressed. De Luc was, no doubt, a zealous friend, but in this letter his zeal outran his discretion. The letter was, indeed, unworthy of him. He hastens to exculpate Lavoisier and La Place, but makes a charge against the honour and integrity of Cavendish, for which there was absolutely no justification. He stirs up Watt's suspicions, and then seeks to appease them; he rouses his anger, and then counsels him to silence by an argument which shows how wholly he misunderstood Watt. Watt's reply was characteristic: "On the slight glance I have been able to give your extract of the paper, I think his theory very different from mine; which of the two is the right I cannot say: his is more likely to be so, as he has made many more experiments, and consequently has more facts to argue upon. . . .

"As to what you say of making myself *des jaloux*, that idea would weigh little; for were I convinced I had had foul play, if I did not assert my right, it would either be from a contempt of the modicum of reputation which could result from such a theory: from a conviction in my own mind that I was their superior: or from an indolence, that makes it easier for me to bear wrongs than to seek redress. In point of interest, in so far as connected with money, that would be no bar; for though I am dependent on the favour of the public, I am not on Mr. C. and his friends; and could despise the united power of *the illustrious house of Cavendish*, as Mr. Fox calls them.

"You may, perhaps, be surprised to find so much pride in my character. It does not seem very compatible with the diffidence that attends my conduct in general. I am diffident, because I am seldom certain that I am in the right, and because I pay respect to the opinion of others, where I think they may merit it. At present *je me sens un peu blessé*; it seems hard that in the first attempt I have made to lay anything before the public, I should be thus anticipated."

There was no desire on the part of anybody connected with the management of the Royal Society to withhold from Watt his just due; and it was eventually arranged that his letter to Priestley, together with one he subsequently addressed to De Luc, should be publicly read to the Fellows, and they were subsequently ordered to be printed in the *Philosophical Transactions* in such manner as their author might desire. By his directions the two letters were merged together, and they appear as having been read on April 29, 1784, under the title, "Thoughts on the constituent parts of water, and of Dephlogisticated air: with an account of some experiments on that subject. In a letter from Mr. James Watt, Engineer, to Mr. De Luc, F.R.S." The greater part of the "thoughts" are concerned with the dephlogisticated air. What relate to water have already been given in the extracts from his correspondence. The terms in the letter to De Luc, as printed in the *Philosophical Transactions*, are substantially identical with those of the letters to Black, Hamilton, Smeaton and Fry.

I have now given all the essential facts which led to the recognition of the true chemical nature of water, and I have stated, as accurately and as impartially as I could, the relative share of Watt, Cavendish and Lavoisier in their discovery and interpretation. As regards Lavoisier, it cannot be claimed that he was the first to obtain the facts. To Cavendish belongs the merit of having supplied the true experimental basis upon which accurate knowledge could alone be founded. Watt, on the other hand, although reasoning from imperfect and, indeed, altogether erroneous data, was the first, so far as we can prove from documentary evidence, to state distinctly that water is not an element, but is composed, weight for weight, of two other substances, one of which he regarded as phlogiston and the other as dephlogisticated air. It would be a mistake, however, to suppose that Watt taught precisely the same doctrine of the true nature of water that we hold to-day. Nor did Cavendish utter a more certain sound. What we regard to-day as the expression of the truth we owe to Lavoisier, who stated it with a directness and a precision that ultimately swept all doubt and hesitation aside—except to the mind of Priestley, whose "random experiment" gave the first glimmer of the truth.

In this respect the conclusion of Lord Brougham is most just. It was a reluctance to give up the doctrine of phlogiston, a kind of timidity on the score of that long-established and deeplyrooted opinion that prevented Watt and Cavendish from doing full justice to their own theory; while Lavoisier, who had entirely shaken off these trammels, first presented the new doctrine in its entire perfection and consistency.

---

[1] Priestley, Cavendish, Lavoisier, and "La Révolution Chimique": the Presidential Address to the Chemical Section of the British Association, 1890; see also "Essays in Historical Chemistry" (Macmillan, 1891).

We thus see that each of these eminent men played an independent and, we may say, an equally important share in the establishment of one of the greatest scientific truths that the eighteenth century brought to light.

As regards Watt, the history of this incident serves to bring out only more clearly what we know to be the true character of the man. It illustrates the vigour of his intellectual grasp, the keenness of his mental vision. At the same time it exhibits his love of truth for truth's sake; his unaffected modesty, and the sense of humility that was not the less real because accompanied by a sense of what his inherent love of rectitude taught was due also to himself. The voice of envy and detraction has not been unheard amongst the strife of partisans in the Water Controversy, but throughout it no syllable has been breathed that reflected even remotely upon his honour and integrity.

SCIENTIFIC SERIALS.

SEVERAL contributions of anthropological interest appear in the January and February issues of *Globus*.—An old Mexican terra-cotta figure in the American Museum of Natural History is described and figured. It was discovered near Texcoco, and represents a warrior in a padded coat of mail. The figure is of life-size, and its workmanship is peculiar to Mexican antiquities.—A description of the temple-pyramid of Tepoztlan, by Dr. E. Seler, contains not only interesting details, but several very good illustrations of the plan and construction of the temple. Tepoztlan is the place where the Mexican kings had their famous pleasure gardens, and the inhabitants have preserved their ancient language and many of their old customs in their mountain home. The temple lies 2000 feet above the town on a cliff. The ruins consist of several buildings of all kinds and sizes, which are suggested to have been the dwellings of the priests. The temple itself has massive walls built of black and red volcanic stone. The inner space is divided into two rooms by a door let in a thick wall. In the inner room was found a rectangular cavity containing coal and two pieces of copal, showing probably that here was the place where the holy fire was burnt. The door leading to the inner room is flanked by two pillars, richly carved, but the most interesting feature of the room is its benches of sculptured stone. In this room stands an idol, and there were found two pieces of sculpture: one a bas-relief painted in dark red, the other a relief of a Mexican king's crown. Altogether, this is a notable discovery; and if it is really the fact that these people have preserved their ancient culture, it is greatly to be hoped that a scientific exploration will be undertaken before it is too late.—Another people of South America is noted in a paper by Dr. Ehrenreich on the Guayaki in Paraguay. Their territory is bounded on the east and south by Parana, on the north by the rivers Acaray and Monday, and on the west by well-wooded hills. Very little is known about them, and only few ethnographical specimens have found their way into museums. The personal possessions of the people consist of a conical-shaped cap made out of a jaguar skin, chains made of pierced teeth and bones of animals, stone axes, bows and arrows, lances made out of the bark of the palm, and a sharp instrument made out of animal bones. Their vessels are particularly remarkable. Some are egg-shaped, and obviously intended to fix in the ground, and most of them belong to the so-called basket pottery. Several illustrations accompany the paper, including three photographs of a Guayaki man. He is very short, with strikingly short legs, long arms, broad shoulders, short neck and large head. They live entirely as huntsmen, without any tillage, and the very primitive character of the race suggests that they, and possibly other tribes on the boundary line of Brazil, would reveal much information of value to the anthropologist.—An account of the Moplahs of the coast of Malabar, by Dr. Emil Schmidt, is exceedingly useful. They are partly of Hindoo and partly of Arabian origin, and the mixture is shown in their customs. In the north the young husband settles in his wife's house, and the woman's right of succession is admitted; in the south, male succession is the rule. A careful study of these mixed peoples is much needed.—Dr. Nehring gives an account of the worship of the ringed snake among the old Lithuanians, Samoyitians and Prussians.—A paper by Mr. C. G. Hoffman, on the Niggers of Washington, contains some notes on the curious superstitious practices of the Voodoo, said to be a survival of the old religion.—Mr. Christian Jensen's paper on the grave mounds and giants' graves in the islands of North Friesland, contains information of special interest to English folk-lorists who have followed Mr. MacRitchie's ingenious explanation of some fairy beliefs.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, March 10.—"On the Relative Retardation between the components of a Stream of Light produced by the passage of the Stream through a Crystalline Plate cut in any direction with respect to the Faces of the Crystal." By James Walker.

If the surface of the plate be the plane of xy, the positive axis of z being directed inwards, the relative retardation is $T(n_1 - n_2)$, where the velocity of light in air is unity, T is the thickness of the plate, and n_1, n_2 are the positive roots of a biquadratic in n obtained by expressing that $lx + my + nz = 1$ is a tangent plane to the wave-surface. Writing the roots of the biquadratic as series proceeding by powers of $\sin i$, and expressing the coefficients (which are linear functions of $\sin i$) as symmetrical functions of the roots, the terms of the series may in general be determined in succession by means of linear equations, and have the form $\pm\alpha' + \gamma$, $\pm\alpha'' - \gamma$, where

$$\alpha = \alpha_0 + \alpha_1 \sin i + \alpha_2 \sin^2 i + \alpha_4 \sin^4 i + \ldots,$$

and

$$\gamma = \gamma_3 \sin^3 i + \gamma_5 \sin^5 i + \ldots,$$

while the relative retardation is

$$T(\alpha' - \alpha'' + 2\gamma).$$

This method fails when the plate is perpendicular to an optic axis, in which case the biquadratic may be written

$$n^4 + (c_0 + c_2 \sin^2 i)n^2 + b_3 \sin^3 i\, n + a_0 + a_2 \sin^2 i + a_4 \sin^4 i = 0.$$

Neglecting the coefficient of n, the roots are

$$\pm(\pi + \rho),\ \pm(\pi - \rho),$$

π and ρ being series proceeding by even and odd powers of $\sin i$ respectively. Assuming that the actual roots are

$$\pi + \rho + \alpha,\ -\pi - \rho + \beta,\ \ldots$$

the successive terms of the series α, β, γ, δ are determined as in the former method, and, as for terms of the fourth order, have the form

$$\alpha = -\gamma = a_2 \sin^2 i + a_3 \sin^3 i + a_4 \sin^4 i,$$

$$\beta = -\delta = a_2 \sin^2 i - a_3 \sin^3 i + a_4 \sin^4 i,$$

so that

$$\Delta = 2T(\rho + \alpha).$$

Geological Society, March 23.—W. Whitaker, F.R.S., President, in the chair.—The Eocene deposits of Devon, by Clement Reid. A re-examination of the area around Bovey has led the author to think that Mr. Starkie Gardner is probably right in referring the supposed Miocene strata to the Bagshot period. Lithologically as well as botanically the deposits in Devon and Dorset agree closely. The gravelly deposits beneath the Bovey pipeclays are also shown to belong to the same period, and not to be of Cretaceous date. This correction has already been applied by Mr. H. B. Woodward to a large part of the area. The plateau gravels capping Haldon are also considered to belong to the Bagshot period, for they correspond closely with the Bagshot gravels of Dorset to the east, and of the Bovey Basin to the west, and possess peculiarities which distinguish them from any Pleistocene Drift. Several speakers took part in a discussion upon the paper, some agreeing with the author's views, and some were opposed to them.—On an outlier of Cenomanian and Turonian near Honiton, with a note on *Holaster altus*, Ag., by A. J. Jukes-Browne. Although an outlying patch of chalk in the parish of Widworthy was mentioned by Fitton and marked on De La Beche's map, it has not hitherto been described. The tract is about 4½ miles south-west of Membury, 3½ miles east of Honiton, and about 7 miles from the coast at Beer Head.—Cone-in-cone: additional facts from various countries, by W. S. Gresley. Examples of flinty stone in the "fire-clay series" of the Ashby coalfield exhibit "areas of conic structure lying unconformably." In the same stratum of shale are large masses of the same flinty rock, more or less coated with conic structures, which appear to have been formed out of layers of shale and ironstone. The bending-up of the shale above the nodules and down below them, the close but unconformable covering of Permian breccia, and the staining of the whole section suggests, if indeed it does not demonstrate, to the author that the growth of the cone-in-cone took place subsequently to the deposit of the Permian breccia. Several American and other examples are described, and a series of conclusions are appended to the paper.

PARIS.

Academy of Sciences, March 28.—M. Wolf in the chair.—Preliminary study of a method of estimating carbon monoxide diluted with air, by M. Armand Gautier. It has been shown in previous papers on the same subject, that carbon monoxide is completely oxidised by passing over iodic anhydride at 60°-65°. The present study is concerned with the dilution at which this action ceases. Known volumes of carbon monoxide were mixed with large quantities of air, and the resulting mixture passed over iodic anhydride; the carbon dioxide product was measured by the method of Müntz. It was found that even at dilutions of 1 in 30,000, the quantity of CO present could be accurately determined. Both acetylene and ethylene are oxidised under the same conditions, but only partially, experiments showing that some 10 to 24 per cent. of the former, and 40 to 60 per cent. of the latter were converted into carbon dioxide.—On the use of palladium chloride as a reagent for the detection of minimal quantities of carbon monoxide in the air, and on the transformation of this gas into carbonic acid at the ordinary temperature, by MM. Potain and Drouin. One part of carbon monoxide in 10,000 of air can be detected by this reagent, if it be assumed that no other reducing gas is present, but the method does not yield quantitative results. Atmospheric air containing $\frac{1}{1000}$th part of carbonic oxide, after remaining in sealed flasks for forty-two days, showed no trace of the monoxide, but a nearly equal volume of carbon dioxide. From this it would appear that the monoxide can be slowly oxidised by air at ordinary temperatures.—*Observations of Perrine's comet* (1898 March 19) made at the Observatory of Paris, by MM. G. Bigourdan and G. Fayet.—Observations of the same comet, made with the large equatorial at the University of Bordeaux, by M. L. Picart.—Observations of Perrine's comet, made at the Toulouse Observatory with the Brunner equatorial, by M. F. Rossard.—Elements of Perrine's comet, by M. J. Lagarde.—Fundamental theorem *on the birational transformations* with complete coefficients, by M. S. Kantor.—On certain linear functional equations, by M. Lémeray.—Researches of precision on the infra-red dispersion of Iceland spar, by M. E. Carvallo. The measurements agree well with the results of earlier researches, but are accurate to another decimal place.—On the rigorous determination of molecular weights of gases, starting from their densities, and the deviations which they exhibit from Boyle's law, by M. Daniel Berthelot.—Gas engines with high compression, by M. A. Witz. A discussion of the theory of the Diesel engine.—On the Hertzian field, by M. Albert Turpain.—On an iodide of tungsten, by M. Ed. Defacqz. The hexachloride is first prepared by the action of chlorine upon the metal, and this heated to about 400° C. in a current of hydriodic acid. The iodide has the composition WI_2.—Quinolinic bases, by M. Marcel Delépine. Heats of combustion and formation of quinoline, tetrahydroquinoline, quinaldine, and tetrahydroquinaldine. Combination of organic bases with certain oxygen salts. Double salts are described of aniline and toluidine with cadmium, zinc, magnesium, nickel, cobalt, and copper sulphates.—New observations on the evolution of the *Urnes*, by MM. J. Kunstler and A. Gruvel.—On the encephalon of the Glyceræ, by M. Ch. Gravier. In spite of certain peculiarities which are related to the considerable length of the prostomium, the encephalon of the Glyceræ present the same fundamental characters as those of other allied Annelids of which the nervous system has been specially studied.—On the relation between centrosomes and vibratile cilia, by M. L. F. Henneguy.—On the structure of the mycorhizia, by M. Louis Mangin.—On the replacement of a principal stem by one of its ramifications, by M. Auguste Boirivant. When a lateral branch replaces a portion of a principal stem which has been destroyed, it undergoes modifications so profound as to finally more nearly resemble, both in its structure and external appearance, the axis which it replaces, rather than the branch *to which it is homologous*.—Biochemical preparation of crystallised dioxyacetone, by M. Gabriel Bertrand. By the action of the sorbose bacteria upon glycerine under suitable conditions laid down in this paper, excellent yields of crystallised dioxyacetone are obtained (25 gr. of the latter from 100 gr. of glycerine).—On the treatment of mania by the injection of normal nerve substance, by M. V. Babes.

HABIT AND INSTINCT.

Habit and Instinct. By C. Lloyd Morgan, F.G.S. Pp. 351. (London: Edwin Arnold, 1896.)

THE substance of this interesting work was delivered in 1896, as a course of Lowell Lectures at Boston, and as lectures in other parts of the United States.

The arrangement of the book is excellent: the first chapter deals with "Preliminary Definitions and Illustrations," the second, third, and fourth with original observations of the author upon the young of many species of birds; the fifth, with observations upon young mammals. These four chapters form the chief material upon which, in the remainder of the volume, a very interesting and important discussion upon animal habits and instincts is carried on, concluding with the consideration, in the twelfth, thirteenth, fourteenth and fifteenth chapters, of the following subjects, which present so many aspects of wide interest:—"The Relation of Organic to Mental Evolution," "Are Acquired Habits inherited?" "Modification and Variation," "Heredity in Man."

In the preliminary discussion in the first chapter a very beautiful example of a complex instinct is afforded in the behaviour of the Yucca moth (*Pronuba yuccasella*).

> "The silvery, straw-coloured insects emerge from their chrysalis cases just when the large, yellowish-white, bell-shaped flowers of the yucca open, each for a single night. From the anthers of one of these flowers the female moth collects the golden pollen, and kneads the adhesive material into a little pellet, which she holds beneath her head by means of the greatly enlarged bristly palps. Thus laden, she flies off and seeks another flower. Having found one, she pierces with the sharp lancets of her ovipositor the tissue of the pistil, lays her eggs among the ovules, and then, darting to the top of the stigma, stuffs the fertilising pollen-pellet into its funnel-shaped opening."
>
> "Now, the visits of the moth are necessary to the plant. It has been experimentally proved that, in the absence of the insects, no pollen can get to the stigma to fertilise the ovules, and the fertilisation of the ovules is necessary to the larvæ, which in four or five days are hatched from the insect's eggs. It has been ascertained that they feed exclusively on the developing ovules, and in the absence of fertilisation the ovules would not develop. Each grub consumes some twenty ovules, and there may be three or four such grubs. But the ovary contains some two hundred ovules. Of these, therefore, say, a hundred are sacrificed to the grubs of that moth through whose instrumentality alone the remaining hundred can be fertilised and come to maturity."

Concerning this elaborate sequence of actions the author points out that they are performed but once in the lifetime of the moth, without instruction, without imitation, and without the guidance which an experience of the subsequent fate of the eggs might provide. The essentially adaptive nature of the sequence is insisted upon.

The relation between what is "congenital" and what is "acquired" is considered in some detail, and by many examples, especially that of the training of falcons, it is shown that the limits of what can be acquired are determined by what is congenital.

> "The behaviour of a trained falcon is an adaptation and modification of the hawk's congenital instincts as a bird of prey. The finished performance is part instinct and part habit. The basis is instinctive and congenital; the modification is a matter of acquired habit."

This valuable preliminary discussion of the subject-matter of the volume is summed up in the following statement—

> "From the biological point of view . . . instincts are congenital, adaptive, and coordinated activities of relative complexity, and involving the behaviour of the organism as a whole. They . . . are similarly performed by all like members of the same more or less restricted group, under circumstances which are either of frequent recurrence or are vitally essential to the continuance of the race. While they are, broadly speaking, constant in character, they are subject to variation analogous to that found in organic structures. They are often periodic in development and serial in character. They are to be distinguished from habits which owe their definiteness to individual acquisition and the repetition of individual performance."

The author has rendered a great service in thus bringing together the essential characteristics of instinct as opposed to habit in a few clear brief sentences.

The interesting experiments of the author upon the activities and instincts of young birds must be read in full to be properly appreciated. They have a most important bearing upon problems of very wide interest, such as the hereditary transmission of acquired characters, the theories of Protective Resemblance, Protective Mimicry, Warning Coloration, &c. These experiments and observations should be studied carefully by all who either criticise or support the above-mentioned theories. The general results only can here be indicated.

The observations of Douglas Spalding (*Macmillan's Magazine*, February 1873) upon young chickens have been much quoted, but many of his conclusions are here shown to be without sufficient foundation. Thus Lloyd Morgan's observations do not support the conclusion that there is any instinctive recognition of the mother hen by the young chick which sees or hears her for the first time. He does not find the accuracy of aim is at first equal to that recorded by Spalding, and he gives strong reasons for the belief that the evidence of instinctive fear of a bee or a hawk is not due to alarm at these animals as such, but merely one example of the extreme shyness of young birds at any unusual sight or sound.

There is no instinctive knowledge of food or water. Any object of suitable size and within the right distance is struck at; but the chicks are very quick in learning from the experience thus gained. A young chick, two days old, which had learnt to select pieces of yolk of egg, twice seized a piece of orange-peel of about the same size and shape. After this he could not be induced to touch it, and for a time refused yolk of egg. The conspicuous caterpillars of the cinnabar moth, alternately ringed with black and yellow, were thrown to some chicks, which seized but immediately dropped them and wiped their bills. Later in the day the caterpillars were again offered, and only tried once by some of the chicks.

The following day, after they had eaten many edible caterpillars, the cinnabars were again thrown to them, but the lesson had now been learnt by nearly all.

> "One chick ran, but checked himself, and, without touching the caterpillar, wiped his bill—a memory of the nasty taste having been apparently suggested by association at sight of the black-and-yellow caterpillar. Another seized one, and dropped it at once. A third subsequently approached a cinnabar as it crawled along, gave the danger note, and ran off. . . . Similarly, moorhen chicks rapidly discriminated between small edible beetles and soldier beetles. Such discrimination is, however, not congenital, but acquired."

This last conclusion is of great importance for the theory of warning colours. If each generation of insect-eating animals has to learn for itself what is fit and what unfit for food, the advantage of conspicuousness to the unfit and of similarity in conspicuousness becomes much greater than under a condition of instinctive discrimination. On this point Lloyd Morgan's numerous experiments seem to leave little doubt. ". . . There does not appear to be any congenital and instinctive avoidance of such caterpillars with warning colours." Of the instinctive avoidance of distasteful insects he says, "I have not found a single instance."

The theory of mimicry, due to H. W. Bates, is also supported by the behaviour of duckling and moorhen chicks which would not touch drone-flies after having been stung by a bee and a humble-bee respectively. There was never any evidence of an instinctive knowledge of the hurtful nature of bees and wasps. A very young bird, after being once stung, is shy for a long time not only of bees, but of various kinds of insects. An older one, after a similar experience, is in the main only shy of the stinging insect and others that closely resemble it.

There is an interesting description of the manner in which the excreta are prevented from fouling the nest, being voided over the edge or carried away by the parent birds. A friend of the author observed that the young of swallows,

> "after being fed by their parents, were nudged and pushed until they turned round and voided excrement, which was immediately seized by the parent bird with the tip of the beak, carried away, and dropped outside."

When the present writer was a boy, he (together with his father and sister) witnessed a proceeding on the part of a parent thrush which made a very deep impression upon him. The parent bird was seen to alight on the edge of its nest, and thrust its beak into the gaping bill and deeply down into the throat of one of its young, and draw forth a large black and white worm-shaped object (apparently from 1½ to 2 inches in length), which it then swallowed. The nest was only a few feet away, below the window of a summer-house, which afforded a perfect view of the performance. It is probable that the observation, which has been up to the present time unintelligible to the writer and those friends whom he has consulted, is to be explained as one form of an instinct of which other forms are recorded here.

The earliest activities in walking, diving, and flying are described in a most interesting chapter which proves the extraordinary congenital accuracy with which these complex associated movements are performed. It is argued with great force that the opportunity of watching the movements of older birds does not offer any sufficient explanation of the precision with which they are performed by the young for the first time. "Who ever learnt to do a difficult thing, even passably well, by merely watching it done superbly by another?" The author's observations convincingly demonstrate the truth of the same conclusion; for he watched the first attempts of this kind made by young birds hatched in an incubator. In all these the earliest associated movements were astonishingly accurate, and sometimes, as in the first dive of a startled moorhen chick (p. 64), incapable of further improvement. Speaking of this example the author says,

> "though long deferred, here was the instinctive activity in congenital purity and definiteness, and absolutely true to type, for this was the very first time he had ever dived, nor had he ever seen any bird do so."

The precision and freedom with which swimming and diving are first performed seems to be much greater than that with which walking and flying are begun. It is not improbable that the difference is due to the further difficulty introduced by the necessity in the latter case, and especially in that of flying, of sustaining the weight of the body, and of starting and checking its movements, for the first time. It is probably this, rather than the coordination of muscular movement, which explains such hesitation and such feebleness as is at first observed. In other words it is probably the considerable strain thrown upon the muscles for the first time which prevents perfect precision, so that when this additional strain of weight is borne by the water, the accuracy of the earliest coordinated movements is much greater. Nevertheless the example of the *Megapodius*, quoted on p. 76, renders it probable that the movements of flight may be performed with complete success immediately after hatching, when they are necessary for the existence of the species.

All these statements and arguments only refer to the power of sustaining and moving the body in the air under the most favourable conditions. For the countless adjustments to the ever-varying currents of wind, it is held that very considerable individual practice is necessary. Flight in its finished form is "the result of practice and individual acquisition . . . founded on a congenital basis" (p. 78).

The conclusions to be drawn from many of these observations on young birds are summed up in a most interesting manner in Chapter iv. Thus, in the case of the associated muscular movements referred to above,

> "what is inherited is a congenital coordination of motor responses under the appropriate conditions of stimulation. Not only is there inherited a given structure of leg or wing, but a nervous system through which there is an automatic distribution of outgoing currents to the several muscles concerned; so that, without learning or experience, they are called into play with nicely graded intensity, and exhibit complex contractions and relaxations in serial order, thus giving rise to instinctive behaviour of an eminently adaptive nature."

In feeding there is

> "a similar congenital coordination of motor responses for pecking at a small object within a suitable distance.

But, from the observations, it seems that the selection of certain of these objects and the rejection of others is a matter of individual experience."

With regard to instinctive fear of particular animals or objects, the evidence indicated that it has no existence in relation to

"bees or wasps as such, but that there is a shrinking response, probably instinctive, from *any* largish strange object, especially if it moves vigorously or makes some such noise as buzzing."

An account of further experiments in the same direction is given in the present chapter. There was no instinctive fear of a fox-terrier dog which was trained to remain passive in the presence of the birds.

"Pheasants, partridges, and plovers would peck at his nose as he smelt at them, and run in between his legs."

"Neither chicks, pheasants, nor jays—not even the little fly-catchers—showed any signs of dread of a kitten, nor did chicks of an older cat."

It is also stated that "there is not apparently much difference in the young of wild and tame birds," in this respect. This interesting conclusion, for which much evidence is quoted, differs from that which has been drawn by Dr. Rae (NATURE, July 19, 1883). The whole of the observations on the effects produced by various animals upon young birds tend strongly to support Mr. Hudson's conclusion that the fear of particular enemies is due to experience and tradition (p. 89).

The rapidity with which associations are formed was illustrated in an amusing manner by some ducklings which had their bath in a tin placed on a tray.

"On the sixth morning the tray and tin were given them in the usual way, but without any water. They ran to it, scooped at the bottom, and made all the motions of the beak as if drinking. They squatted in it, dipping their heads and waggling their tails as usual. For some ten minutes they continued to wash in non-existent water, the coolness of the tin to their breasts perhaps giving them some satisfaction."

However, the next day they soon gave up the attempt, and "on the third morning they waddled up to the dry tin and sadly departed" (p. 96).

The congenital nature of the movements in bathing were well shown by jays and magpies. One of the latter was observed by Mr. Charbonnier "to go through all the gestures of a bird bathing" upon the floor of the cage, after pecking once or twice at the surface of water in a pan with which it had been supplied for the first time.

Some of the main general conclusions will be found summarised in seven short paragraphs at the end of Chapter iv.

The succeeding chapter deals with the young mammal. The immense difference in the activity of the newly-born young of various mammalian groups is well brought out by numerous interesting examples.. Chief among the congenital associated movements of the young mammal is the act of sucking, in response to the contact of any solid substance of suitable size with the mouth. A more striking instance of the purely reflex and congenital nature of the performance, than any as yet recorded, was described to the present writer by Dr. J. Sidney Turner.

"There is no doubt whatever," Dr. Turner writes, "about the sucking reaction before birth (*i.e. before* the instinct can be in any way useful—indeed it would be the *reverse* of useful). During the process of cephalic version which is done whilst the fœtus is high up in the uterus, I have, on several occasions, placed my little finger in the mouth of the fœtus, and it has most distinctly sucked the finger exactly in the same manner as a born baby would do. . . . I don't know at what age of the embryo fœtus sucking is possible, but I know that a six months fœtus, at birth, can suck well."

It is satisfactory to be able, with Dr. Turner's permission, to put on record this interesting observation upon the human species, an observation which may well be added to the numerous others given in Chapter v.

The conclusions of Spalding and others that the kitten recognises and shows an instinctive fear of the smell of the dog are criticised, and the true inference is shown to be probably as in the case of the chick, the characteristic behaviour being only an example of congenital response to almost any strong stimulus. The responses in later life are explained as the results of experience and of parental influence. Prof. Lloyd Morgan freely admits that "there may be an instinctive basis, however, in some cases where animals are by nature enemies." The behaviour of the frog in presence of the grass-snake and of the rabbit in presence of the stoat would be especially interesting to investigate from this point of view.

It is well pointed out in this chapter that however much instincts are

"utilised, modified, and adapted through experience and acquisition, yet the fundamental distinction between that which is congenital and instinctive, on the one hand, and that which is acquired through individual experience, on the other hand, remains unaltered. . . . The instinctive action is prior to experience; the acquired action is due to experience. And this distinction holds, no matter how hard it may be to decide whether this action or that is in the main instinctive or in the main acquired."

These earlier chapters, which are full of interesting observation and acute criticism, have been drawn upon to a considerable extent in this notice; but all who are interested in the subject are bound to study the original. The limits of space prevent any further reference to the close reasoning in the important chapters which deal with the material supplied by these observations, and out of it construct for us valuable theories of animal psychology and the mode of the working of the higher parts of the nervous system in relation to instinct, intelligence, imitation, emotion, &c. It is sufficient to say that to most, probably to all, naturalists who are accustomed to reflect on such subjects the conclusions will commend themselves as those which are to be legitimately drawn from the facts.

In the interesting chapter on "Some Habits and Instincts of the Pairing Season," the author protests strongly against "the unnecessary supposition that the hen bird must possess a standard or ideal of æsthetic value, and that she selects that singer which comes nearest to her conception of what a songster should be." It may be conceded that the word "æsthetic" is an unfortunate one to use in this connection. On the other hand, the comparison between the chick which "selects the worm that excites the strongest impulse to pick it up and eat it" and the hen which "selects that mate which by his song or otherwise excites in greatest degree the mating impulse," although doubtless perfectly true in itself, leaves unexplained and indeed unexpressed the fact that the song or plume which excites the mating impulse in the hen, is also in so high a proportion of cases most pleasing to man himself. And not only this, but in their past history, so far as it has been traced (*e.g.* in the development of the characteristic markings of the male peacock and argus pheasant), such features have gradually become more and more pleasing to us as they have acted as stronger and stronger stimuli to the hen. Why should this be?

In the chapter on nest-building, incubation and migration, there is a most effective reply to those (and they are many) who point to the "coincidence" that "congenital variation on the one hand, and intelligent choice on the other, coincide in direction and tend to the same result," as almost too much to be believed except on the supposition that the latter has through heredity given rise to the former. To this argument the author replies that both these principles are

> "working, in their different spheres, towards the same end—that of adaptation. . . . Is it a coincidence in any proper sense of the term? Surely not. If two men start for the same place, the one by sea and the other by land, we should not regard it as a coincidence if both got there."

A number of interesting facts are quoted about bird migration, and the author surmises, but very cautiously, that

> "while the migratory instinct is innate, and perhaps there is an instinctive tendency to start in a given direction, yet the element of traditional guidance may be effectual, in the migratory stream as a whole, in some way that we have hitherto been unable to observe" (p. 261).

The onus of proof seems certainly to rest with those who dispute this latter conclusion, and who hold so inherently improbable a view as that there is an instinctive knowledge, prior to experience, of geographical routes of enormous length and devious course. A single observation recorded by W. Warde Fowler (in the *Midland Naturalist*) a few years ago, points very strongly in the opposite direction. Mr. Fowler was standing on the English coast just opposite the western end of the Isle of Wight, but the day was misty and the island invisible. He watched the successive companies of swallows sweeping by eastward to join the migratory stream to the south, and he saw that each company followed the circuitous coast-line leading north of the island. All at once he noticed a change: a company arriving at the spot where he was standing, rose in the air and then flew to sea in an eastward direction. He then turned and saw that the mist had cleared and the island was visible. The birds were now able to take the shorter route, for they could see the way.

With regard to the question "Are acquired habits inherited?" the author in the thirteenth chapter, after a keen criticism of the evidence concludes, but with much caution, that "there is but little satisfactory and convincing evidence in favour of transmission." The appearances which have suggested an opposite conclusion to many writers are explained in the next chapter, "Modification and Variation." We have here an exposition of a most interesting and useful suggestion independently made by the author, Prof. Osborn of New York, and Prof. Mark Baldwin of Princeton. Others (*e.g.* Prof. Weismann) have previously laid more or less stress upon the same principle, but it has been due to the writings and influence of these three authorities that the matter has been put in its true light, and the principle shown to be an important contribution to organic evolution. This principle, which has been described in America by the not very self-evident term "organic selection," is thus explained by Prof. Lloyd Morgan in the work now referred to.

> "If now it could be shown that, although on selectionist principles there is no transmission of modifications due to individual plasticity, yet these modifications afford the conditions under which variations of like nature are afforded an opportunity of occurring and of making themselves felt in race progress, a farther step would be taken towards a reconciliation of opposing views."

A case is then considered: suppose there is a change of environment and the congenital variations are not equal to the occasion, "individual plasticity steps in to save some members of the race from extinction . . . through a modification of the bodily tissues." In this way time is given for the appearance of congenital variations in the same direction, which is therefore rendered possible by the power of individual modification.

> "Thus, if the conditions remain constant for many generations, congenital variation will gradually render hereditary the same strengthening of . . . structure that was provisionally attained by plastic modification. The effects are precisely the same as they would be if the modification in question were directly transmitted in a slight but cumulatively increasing degree; they are reached, however, in a manner which involves no such transmission." In this way "we may accept the facts adduced by the transmissionist, and at the same time interpret them as selectionist principles."

This principle is, in the opinion of the present writer, a valuable aid in the attempt to understand the evolution of the organic world. It should be observed, too, that the author does not intend any part of this principle as a substitute for natural selection; for he fully recognises that the "innate plasticity" is as much a product of natural selection as "congenital definiteness" (p. 319).

The last chapter deals with "Heredity in Man"; and here the author concludes that

> "mental progress is mainly due, not to inherited increments of mental faculty, but to the handing on of the results of human achievement by a vast extension of that which we have seen to be a factor in animal life, namely tradition."

In his final summary he states that

> "there is little or no evidence of individually acquired habits in man becoming instinctive through heredity. Natural selection becomes more and more subordinate in the social evolution of civilized mankind; and it would seem probable that with this waning of the influence of

natural selection there has been a diminution also of human faculty. Hence there is little or no evidence of the hereditary transmission of increments of faculty due to continued and persistent use. A discussion of heredity in man thus confirms the inference drawn from the study of habit and instinct in some of the lower animals."

Those who disagree with any of these conclusions are invited to study carefully the strong arguments by which they are supported.

Further discussion of many of the interesting questions raised in this valuable work would have been desirable, but the limits of space forbid. Enough has been said, however, to show that this book compels the serious attention of all who profess to feel an interest in the instincts and habits of animals.

The printing and general get-up of the volume leave nothing to be desired. There is one excellent plate forming the frontispiece, representing a group of the young birds employed in the recorded observations, drawn by G. E. Lodge. E. B. P.

TRAVELS IN INDO-CHINA.

From Tonkin to India by the Sources of the Irawadi. By Prince Henri d'Orléans. Translated by Hamley Bent, M.A. Illustrated by G. Vuillier. Pp. xii + 467. (London: Methuen, 1898.)

FROM the time of the great expedition under Doudart de Lagrée, which in 1866–68 threw such a flood of light on the countries watered by the great Mekong River, and of which the story was so admirably told by the lamented Francis Garnier, the exploration of the eastern half of Indo-China has fallen almost entirely to Frenchmen, who with untiring energy have traversed its jungles, and by their successful enterprise have added an empire to the dominions of the French Republic. But in spite of the labours of these devoted pioneers, and of the equally zealous explorers who, from the British side, have sought to disclose the mysteries of that long-closed region, there still remained an inner recess, as it were, to which no European had succeeded in penetrating. The region in question had for many reasons possessed a singular fascination for geographers. Traversed, to use the words of the late Sir H. Yule, by "that formidable fascis of great rivers, descending from the highlands of Tibet, which give to the map of this region an aspect so unique in geography," it engaged attention not only from the various problems connected with the courses of those rivers, but from the remarkable barrier which it placed in the way of communication between the neighbouring countries of India (Assam) and China, a barrier so effectual that the same high authority, writing in 1883, could adduce only three instances in which it had been pierced during our own times, even by a piece of intelligence. It was reserved for Prince Henri d'Orléans, who had already made himself known by several enterprising journeys, to be the first to cross this barrier, in company with MM. Roux and Briffaud, and his lately-published narrative may be said without hesitation to have fully deserved the honours of a translation, such as is now before us.

Prince Henri's journey naturally falls into three sections, the interest of which may be said to stand in an ascending ratio. In the first, a little-known region lying on the borders of Southern Yunnan and Tonkin was traversed from east to west, the route terminating at the interesting Chinese town of Sumao, famous as the centre of distribution of the so-called "Puerh" tea, grown in the Shan country to the south. The second, of which the direction was mainly from south to north, was concerned with the exploration of a section of the Mekong, for a knowledge of which we were previously dependent solely on old Chinese maps, with the one exception of the crossing-point of the road from Burma to Yunnan. The river was struck at a point somewhat to the north of Kiang (or Xieng) Hung,[1] reached from Maulmein by McLeod in 1836, and likewise the last point at which the river was seen by Lagrée and his companions. From here, with the exception of a detour to Tali-fu and a minor deviation into the neighbouring Salwen basin, the valley of the Mekong was followed as far as the French mission stations in South-eastern Tibet, through the countries of the Lamasjens, Lissus, and other wild and imperfectly known tribes. The third and last section, in which the westerly direction was resumed, led across the previously unpierced barrier between China and Assam, the region of the Irawadi head streams, the system of which had been previously the subject of so much controversy among geographers. The starting-point for this section was the mission station of Tseku, the furthest point reached by Mr. T. T. Cooper, when he, too, nearly thirty years ago, made his first daring attempt to traverse the same, then impenetrable barrier.

The country traversed by this route was of such a character as to try the mettle of the hardiest of explorers. The great rivers, as is well known, flow in parallel courses, separated by steep mountain ranges, up which the traveller must climb by the most difficult of paths, which often run sheer above the foaming torrent rushing many hundred feet below him. The Prince's party were provided with a caravan of mules, and even these sure-footed beasts would occasionally lose their footing and roll down the steep mountain-side. They seem also to have had a propensity to stray, which entailed many an arduous search.[2] No less arduous were the marches through the trackless, dripping forests of the Upper Irawadi basin. The crossing of the rivers, too, often involved serious difficulties. The Mekong is provided in places with iron chain-bridges, the vibration of which demanded a steady nerve in the crossing; but this was nothing to the actual danger involved by the passage of rushing streams on frail rafts or by slippery bamboo bridges, or those consisting, after the Tibetan fashion, of a mere rope, down which the passenger shoots with lightning rapidity. The trusty interpreter Joseph, a convert of the missionaries at Tali, who, with his nondescript Latin (his only medium of communication with the travellers), supplies many humorous touches, "loved not water frolics," and would utter a fervent *Deo gratias* when the danger was safely past. This man proved a valued and faithful servant, and, sharing all the dangers and vicissitudes of the way, was finally regarded rather in the light of a friend than a dependent.

---

[1] Prince Henri is in error in saying that a railway is in course of construction to Kiang Hung from Mandalay. Although schemes have been set on foot for the reaching of this place by railway from Siam and Lower Burma, the railway from Mandalay is to make for the Kunlon ferry across the Salwen, and to reach the Chinese frontier through the state of Kokang, lately ceded to Great Britain.

[2] A strange kind of fodder, given to them by the drivers, on the recommendation of the Tibetans, was a hash of raw fowls and salt, said to be a rare pick-me-up for beasts of burden.

Apart from the surface forms, the vegetation offered much of interest to the explorers, and its varied aspects—from the tropical forests of the lower valleys, to the woods of superb coniferæ on the mountain slopes, and the alpine flowers of the higher passes—are brought vividly before us as we read the Prince's pages, which describe some charming scenes. We read, *e.g.*, of cool forests "where white dog-roses scaled the trees and drooped in fragrant clusters over dazzling diadems of lilies of the height of a man, and under foot pink primulas made a gay carpet." Much valuable information is given, too, with respect to the aboriginal tribes above alluded to, as well as the Lolos of the extreme south of Yunnan, of whose manuscripts a fair number were obtained. Several specimens of the hieroglyphic writing of the Mossos on the Tibetan border were also procured, and the meaning of some of them, hitherto obscure, was explained by the magicians by whom the books are made. The Mossos and the Lolos are said to have probably had the same origin, belonging to the Tibeto-Burmese family; the Lissus also speak a dialect resembling that of the Lolos. Among the Minchias and Lissus some individuals seemed to have little in common with the yellow race, and one Lissu woman reminded Prince Henri of Russian gipsies. Vocabularies of the languages of all these tribes are given in an appendix; but we do not find any comprehensive summary of their affinities, which would have been of much value.

A word must be devoted to the illustrations, with which the book is liberally provided. Their authority is not stated in the English edition, but from the French title-page we learn that they are from the author's photographs. It is doubtful, however, whether the artist has not in many cases allowed himself considerable freedom in their reproduction, especially in the somewhat sensational incidents represented. The translation is, on the whole, excellent; but a few errors of the French edition with regard to proper names have been retained. Thus we find Rochill for Rockhill, likewise Bonnin, Manhat, Néris, and Aymard, presumably for Bonin, Mouhot, Neis, and Aymara, which shows the need of revision by one acquainted with the subject treated. For English readers the French spelling of geographical names should have been modified. It requires an appreciable amount of time to recognise the pronunciation of some in their unfamiliar garb, as, *e.g.*, when In-shwan is written In-chouan. According to the prevailing French fashion the spelling Thibet is retained. This has, it is true, the authority of M. Desgodins, but others of his countrymen have held the *h* to be incorrect, or at least unnecessary. (Cf. *Comptes rendus*, Paris Geographical Society, 1887, *passim*.)

Taken as a whole, however, the book forms a worthy record of an important journey, and the interest of the narrative is well sustained from beginning to end.

INJURIOUS INSECTS DURING 1897.

Report of Observations of Injurious Insects and Common Farm Pests during the Year 1897, *&c.* By Eleanor A. Ormerod. Pp. viii + 160. (London: Simpkin, Marshall, and Co., Ltd., 1898.)

THE publication of this, the twenty-first of these annual reports, will prove, as heretofore, welcome both to agriculturists—for whom primarily they are intended—and to those interested in a public-spirited and isolated attempt to grapple seriously with problems of State entomology in this country.

Of insect attacks to field crops during 1897, no cases of the first importance are recorded; the Cabbage-aphis (*Aphis brassicæ*) and Silver Y-moth (*Plusia gamma*) were locally destructive, the latter to mangolds in Co. Kerry, and attack of the Diamond-back moth (*Plutella cruciferarum*) on turnips was again reported, this time from various spots on the east and west coasts of Scotland. As has so often been the case of late years, nematode disease of oats and clover was troublesome.

During the last few years the strawberry crop has suffered badly from two species of ground-beetles, *Harpalus ruficornis* and *Pterostichus vulgaris*, which have acquired the habit, singular in carnivorous insects, of feeding on the unripe and ripe fruit. The infestation has occurred in several counties, ranging from Nottinghamshire and Hertfordshire to Gloucestershire, and causes much loss and anxiety to growers. No satisfactory mode of prevention is known, and recourse is generally had to methods of trapping the imagos. Evidently, the breeding habits and mode of life in the larval stage should be more fully studied; the suggestion, sometimes made, that the insects are conveyed with manure, is somewhat improbable, and needs proof.

In 1889, much interest was aroused among entomologists by the attacks on plum-trees of a Scolytid beetle, *Xyleborus dispar*, previously a very rare species in Britain. Curiously enough, Miss Ormerod now records a severe infestation of the same orchards by a second species, *X. xylographus* (*saxeseni*). The subject is dealt with at length, but without fully establishing the culpability of *X. xylographus*, itself rather a scarce species in England, and one not usually associated with injury to healthy trees. *X. dispar* was also present in small numbers, and the coexistence of these species, so often found in association on the continent, may point to a possible importation. These attacks deserve further careful study; the relationship between Scolytid infestation and the health of the host-plant, however obscure, should never be disregarded or minimised, and the author's singular statement, that she knows of no difference between the perforations in trees made by each species, proves that their respective shares have not been properly evaluated.

Amongst other enemies to trees, *Cryptococcus fagi* has proved very injurious to beech at Burton-on-Trent. Common as it is, it is seldom so markedly destructive. Treatment is difficult, as insecticide dressings cannot always be profitably employed on trees of so large a size.

The report contains articles on several granary insects, including the Angoumois moth, *Sitotroga cerealella*, which is probably often imported in grain, without establishing itself permanently in the country; and among subjects of minor importance, cockroaches, earwigs, and the like, may be noted the importation of dead locusts in some numbers in fodder from the Argentine Republic. There is evidence that their consumption has caused injury to horses, perhaps through mechanical irritation. Needless to say, Miss Ormerod does not encourage the idea that the introduction of live locusts, which in small numbers is almost an annual occurrence, is likely to cause an invasion.

It must, we imagine, be a source of regret to the author that the example she sets does not lead to a more thorough study of our insect pests. In many cases, the good that can be done by a referee, restricted as to opportunities for field observation, and depending largely on the capacity and good-will of correspondents, soon reaches a limit, which requires to be extended by broader methods of inquiry on the lines which have been so well developed in the United States. And it is satisfactory to note that the economic treatment of that very troublesome pest, the Currant Gallmite, discussed in a special appendix, is now being made the subject of extended research at the Woburn Experimental Fruit Farm. W. F. H. B.

OUR BOOK SHELF.

Elements of Comparative Zoology. By J. S. Kingsley, S.D., Professor of Zoology in Tufts College. Pp. 344, small 8vo.; with 148 illustrations. (New York: H. Holt and Co., 1897.)

The reputation of the author of this little book justifies the expectation of novelty, and in this we are not disappointed. The work, which has a local flavour, is based upon a conviction expressed in the preface, that while "laboratory guides are somewhat numerous . . . general outlines of zoology adapted to beginners are few," and that "nature studies are truly educational only when the student is trained to correlate and classify facts." Imparting a knowledge of the zoological alphabet by the now universally adopted Huxleyian method, the author proceeds to supplement that by a sort of reading lesson, in the form of a very brief outline of some of the chief structural limitations and ordinal characters of each group of which a typical species has been previously more fully examined, leading thus up to class distinction and the definition of phyla. In this manner the gnathostomatous vertebrata are first taken in hand in ascending order, and next the invertebrata in descending; and after a short chapter on each of the great animal sub-kingdoms, the work concludes with others on the metazoa, protozoa, comparative physiology, morphology, and on the animal kingdom. The practical mode of elementary instruction in biology by the type-system was never intended to go unsupplemented; and while the plan here adopted is one which must have been elsewhere in vogue, as the natural result of the growth of the system, to the author is due the credit of having first developed it in print. His chief novelty lies in the substitution of an interrogatory for the time-honoured didactic mode of treatment of the practical portion of the subject, with the introduction of a series of "Comparisons" in the form of questions which make for correlation of ideas. A very ingenious departure! but we would rather await the verdict of time upon it than pronounce outright. Fair consideration is given to habit, distribution, and other topics where desirable; and the book, though thin, is on the whole trustworthy and fairly up to date, its weakest part being the physiological, the few short pages devoted to which are hackneyed and behind the times. A goodly amount of sound advice is scattered throughout the introduction and the text. The illustrations are very unequal, Fig. 63 being a positive burlesque on nature, Fig. 25 antiquated and useless, and Fig. 69 erroneous, by lack of knowledge of the large series of observations finding their focus in Boas's discovery of a prepulmonary aortic arch in the frog's tadpole. As leading error may be cited the allegation concerning the function of the marsupial bones, and as ill-advised the adoption of the Hæckelian classification of birds. In formulating so common-place a system as the dental of the dogs, the author has gone astray; and special interest attaches to the remark that he, an American, should write of the Ruminantia Cavicornia that their "horns are never shed," and give, in illustration of this assertion, a picture of the American Prongbuck, notorious as the only exception to that rule! We would recommend the consideration to the zoological brotherhood.

The Tutorial Chemistry. Part ii. *Metals.* By G. H. Bailey. Pp. 300. (London: W. B. Clive, 1897.)

The present volume is intended to supply the student with his second year's course of study, the first year having presumably been spent over the "non-metals." The first section, occupying about one-third of the book, deals with chemical physics, the remainder being taken up with the systematic description of the commoner metals. There are three appendices, dealing with crystallography, spectrum analysis, and some suggested experiments. The section on chemical physics commences with a description of the methods available for the determination of atomic weights, this being followed by a discussion of the relations existing between the numbers thus found and the physical properties of the elements. Chapters iv. and v. deal with dissociation, specific volume, and the optical properties of liquids. The chapter on solution is the largest in the section; but the treatment of this important branch of the subject is not so satisfactory as that of the other portions dealing with physical chemistry. Thus, while a considerable amount of space is devoted to the hypothesis of Grotthus, which the student will afterwards have to unlearn, the work of Hittorf is not mentioned, although the latter forms the keystone of the modern theory of solution.

In spite of the great compression necessary, only 150 pages being allotted to a description of some fifty elements, the latter portion of the book gives a clear and concise account of the preparation and properties of the metals, each group being preceded by a summary of the reactions common to its constituents.

The classification of Mendeléeff is adopted throughout; and since the clear exposition of the periodic law requires the inclusion of certain of the "rare" metals, such elements as gallium, indium, thallium and uranium are described in their proper places along with commoner elements, instead of being relegated to a kind of museum of curiosities in the form of an appendix—a practice unfortunately usual with the smaller text-books.

The Kingdom of the Yellow Robe: being Sketches of the Domestic and Religious Rites and Ceremonies of the Siamese. By Ernest Young; with illustrations by E. A. Norbury. Demy 8vo. Pp. xiv + 399. (Westminster: Archibald Constable and Co., 1898.)

The author has had the advantage of several years' residence in Siam, during which time he learned the language, and his educational duties enabled him to observe the working of the native mind. He writes with an evident sympathy for the common people; and in his sketches of the every-day life of the capital, he has caught not a little of the humour which is one of its chief characteristics. He discourses pleasantly on street and canal scenes, and explains at some length many of the more important ceremonies by means of which Siamese Buddhists make the amount of "merit" necessary for the bettering of their position hereafter, and he gives a short account of the Buddhism of the country. The author makes some interesting observations on education, and gives an attractive picture of the children with whom his duties brought him in contact. He does not go far beyond the capital, and the scattered remarks about the interior do not enlighten the reader much as to the commercial aspects of the country. Politics have also been rigorously excluded. On the whole there is not much which may not be found in Turpin, Crawfurd, Bowring, or Alabaster, or in the recent writings of Captain Gerini. The author does not, however, pretend to an entirely original or exhaustive treatment of the subject. His aim has rather been a chatty and popular account of the life and ideas of the ordinary people, as they present themselves to the observant resident of Bangkok. The Far East is daily coming nearer, and becoming more intelligible, to the Western reader, and the present work is one which, in our opinion, distinctly helps to bridge the gulf which yet lies between them.

The illustrations, which, it is no discredit to the author to say, form the chief feature of the book, are by Mr. Norbury, another old Bangkok resident. Some of these, especially the full-page drawings towards the end of the book, are quite charming, and give some characteristic scenes with a rare combination of fidelity and artistic effect.

The West Australian Settler's Guide and Farmer's Handbook. (Perth, W.A.: Wigg and Son, 1897–98.)

West Australia is at the present time best known to us by its gold mines; the real importance of this vast and almost unoccupied territory must, however, be determined by its capability of supporting in the future a large population, and hence the agricultural capabilities of the country become an extremely important factor in any schemes for its development. The Handbook before us is issued by the Agricultural Department of the Colony; its object is to present a picture of the agricultural capabilities of various districts, and to advise intending settlers as to their best course of action. It deals chiefly with the south-western portion of the Colony, a district enjoying a better and more uniform rainfall than is generally met with in Australia, and the general fertility of which is vouched for by the occurrence of large areas of heavily-timbered land. The forests of West Australia are said to occupy more than forty million acres; the wood from them has already been employed in paving London streets. Large areas of the country appear to be especially adapted for vine culture. Part i. of the Handbook describes the agricultural areas open for selection. Part ii. contains general instructions for settlers. Part iii. deals with the natural grasses and weeds, and with various imported crops. Part iv. is devoted to sheep husbandry. Part v. is a general treatise on soils and manures, without much special reference to Australia. The whole publication is freely illustrated. The photographs of the forest trees are very striking. The maps are bad, and quite insufficient for the purpose. The Handbook has evidently been hastily put together, and its value is often marred by the want of a clear arrangement of the subjects discussed. R. W.

Die Gattung Cyclamen *L. eine systematische und biologische Monographie.* By Dr. F. Hildebrand. Pp. 190, with 6 plates. (Jena: Gustav Fischer, 1898.)

Living plants have served Dr. Hildebrand as the basis of his careful study of the genus *Cyclamen*, and herbaria have afforded additional material. The result is a most thorough monograph of the genus, the thirteen species of which have been studied in great minuteness. Eighty pages are given to the description of these, and the remaining portion to a general review of the genus. The book is extraordinarily free from theory; indeed, it is a storehouse of facts.

One species of this genus, *C. persicum*, has recently been brought forward as affording a good instance of the gradual accumulation of small variations, which has yielded the many forms in cultivation. For this reason it has a special interest; and Dr. Hildebrand's assertion of the variability of the wild plants (p. 166), and his recognition of no hybridisation of this species, come as opportune remarks. Variation in the leaf has particularly attracted the author's attention; and he notices, too, that there can be traced no connection (p. 172) between the variability of the foliar and floral organs.

Of biological interest are such statements as the following: that the corms have for a protection some poisonous substance (p. 92); that the leaves have no character in them which will definitely support Stahl's theory of the relation of their shape to rainfall (p. 110); that the pollen, at first sticky, becomes dry and powdery (p. 132); that ants appear to aid in the dispersal of the seeds (p. 142); and that the corm begins to form very early in germination (p. 11). From these the general trend of the book may be judged; but, in addition, anatomy, teratology, distribution, and the relation of the species to their habitat, the rest of the seed, age of the plant at flowering, colour of the leaves, &c., find a place. The whole results in a most careful work, which, unfortunately, wants a good index. I. H. B.

An Arithmetic for Schools. By S. L. Loney, M.A. (London: Macmillan and Co., Ltd., 1898.)

This is a comprehensive text-book clearly written and well arranged. There is a useful chapter on abridged methods and approximations, and a note (in the appendix) on the metric system. Compound interest is, very properly, done entirely by decimals. The examples are numerous, sensibly chosen, and carefully graduated. The term "concrete number" is objectionable; so is the statement "1 lb. of sugar = 2*d.*" in the explanation of the chain rule. In compound proportion too much of the old-fashioned paraphernalia has been retained; and we think that too much attention has been paid to the conversion of vulgar fractions into recurring decimals, and *vice versâ*. It would be a good thing if recurring decimals could be eliminated from all elementary examinations in arithmetic; they are of no practical use, and the tiresome calculations connected with them help to perpetuate the English prejudice against the metric system. It may be worth noticing that in Chapter v. the term "power" and the index notation are apparently introduced without previous explanation. In some cases it would be well to give not only an explanatory working of an example, but also the actual computation, arranged in proper form. It is true that this is done in many cases; but there are many others where the working is decidedly clumsy, owing to the addition of explanatory matter. On the whole it may be said that this work, while not specially distinguished by novelty of treatment, deserves to rank with the best of its class. G. B. M.

Navigazione Aerea. By Guglielmo N. Da Pra. Pp. 73, with 18 woodcuts and 6 plates. (Milan: Ulrico Hoepli, 1898.)

This is a critical examination of the various conditions which must be satisfied by a flying machine, together with designs of proposed arrangements of aeroplanes to be worked by means of benzene motors symmetrically arranged.

On the principle that "an ounce of practice is worth a pound of theory," it will be interesting to see how far Signor Da Pra's predictions as to the form of the flying machine of the future are confirmed by future experiments. G. H. B.

Lessons with Plants. By L. H. Bailey. Pp. xxxi + 491. (London: Macmillan and Co., Ltd., 1898.)

Though written for the use of teachers and students of botany in North America, this book will be found almost as useful on this side of the Atlantic. Very many of the plants employed as examples are either natives of, or very generally cultivated in, the British Islands, and could easily be obtained both in country and in town. Even where the selected examples are not themselves readily procured among us the methods of study, the lessons drawn from them, and the suggestions offered for further personal investigation, are very often such as could be readily applied by an intelligent reader to British species.

The author very consistently carries out his method of instruction. He assumes that the pupil is absolutely ignorant; and taking familiar objects, such as an apple-twig, he shows simply and well the information that can be read in them by the trained eye and mind. The book is admirably fitted to give training in the methods of observation, in so far as that can be given during school-life. It should be of peculiar value to teachers if used (as the author, in the introduction, points out that it is meant to be) to suggest how lessons can be drawn from any and every plant. One cannot read many pages without realising that the careful observation and accurate knowledge gained by the teacher that works out examples in the manner followed here will enable him to make the subjects taught by him very real and living. It is the true scientific method applied to the first steps in botany. To the beginner in the science, also, who wishes to learn, but cannot obtain systematic instruction, this book would be an excellent introduction. If each section were read with the actual specimens in hand, and compared with the description step by step, and, still more, if the "suggestions" were followed out practically, the student would have gained a very valuable training, and a trustworthy foundation on which to build up the wider study. The method followed is naturally somewhat informal; but it allows of many sides and applications of botany being touched on in a way to awaken the interest of pupils; and the information conveyed is of a kind that does not require to be unlearned, but can be built up into its proper place as the study becomes more systematic. Occasionally one feels that the explanation is insufficient, and that it must leave a vagueness in the mind of a beginner, as, for example, where we are told that it is "the custom of botanists" to "say that when either floral envelope is wanting it is the corolla (unless there is some special reason to the contrary). This is, generally, an arbitrary definition, but it would be just as arbitrary to say that the sepals are missing." It is scarcely "evident" in respect of the ligulate flowers of the dandelion and Rudbeckia "that if the corolla of a floret were to develop to such a length, it could not spread equally in all directions, as a mathematical calculation will prove; it therefore develops in one direction, as a leaf does." The description of the flowering spurge would scarcely be clear to a beginner. But such defects are so inconspicuous as to detract little from the value of the book, which is enhanced by many excellent original "delineations from nature."

Ethnological Studies among the North-West Central Queensland Aborigines. By Walter E. Roth. Pp. xvi + 199, and Plates. (Brisbane: Gregory, 1897.)

The chief difficulty which an investigator has to surmount in studying the habits and customs of a savage race is their innate suspicion, which often prevents them relating not only the traditions of their tribe, but also their common customs.

Roth claims to have overcome this difficulty by a prolonged residence among the natives of North-West Central Queensland, and states that it was not until he was fully conversant with their language that he could acquire sufficient confidence from the natives to learn their customs.

As an aid to future explorers, he begins his book with an elementary grammar and vocabulary of the language spoken in the Boulia district: a table is added, comparing the words in common use in adjacent districts.

This race communicates ideas by signs as well as sounds; the origin of the actual manual movements is usually easy to trace, and lucidity is added to the description by illustrations. Social and individual nomenclature among these races is developed to such an extent, that careful study of an admirable chapter devoted to the question is necessary for the reader to fully comprehend that intricate organisation.

Roth describes the food and the method of obtaining and preparing it; the recreations and amusements of the people. Cannibalism, he states, is practised in the Boulia district; but a person is never slain for the purpose of supplying food, nor may any but relatives partake of a corpse.

The last chapter is devoted to descriptions of initiation ceremonies, which are often too gruesome to dwell upon in detail. The book consists of a description of a number of facts; the origin and development of customs is but rarely attempted.

L'Électro-chimie. Production électrolytique des Composés chimique. By A. Minet. Pp. 167. (Paris: Gauthier-Villars et Fils; Masson & Cie.)

This little work is a volume of the well-known "Encyclopédie Scientifique des Aide-Memoire," and is devoted mainly to the industrial applications of electrolysis other than those of which the object is the preparation of metals. The chapter dealing with the electrolysis of solutions of sodium and potassium chlorides, which gives a good account of the more important processes which have been proposed for the preparation of caustic alkalis, hypochlorites and chlorates, may be specially commended. The attempts which have been made to employ electrolysis in purifying and ageing alcoholic liquids, in tanning, and in purifying sugar, are described, as well as a number of minor applications of the electric current.

"Théories de L'Électrolyse" (pp. 175) is another volume of the same series as the above, and by the same author. It gives a sketch of the theory of the voltaic cell, of the constitution of electrolytes and gases, and of osmotic pressure. Electrolytic conductivity and the migration of the ions are also treated at some length. The researches of the author's fellow countrymen are rather fully, though not always clearly, described, the work done in other countries receiving very inadequate treatment.

LETTER TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature, *No notice is taken of anonymous communications.*]

Malformed Crabs.

In your issue of March 10 I observe a most interesting letter from your correspondent, Mr. R. I. Pocock, regarding a malformed specimen of *Cancer pagurus* in the Dover Museum. I have never seen such a remarkable case of malformation in the common edible crab, but in the Robertson Museum here is to be seen a very fine specimen of *Nephrops norvegicus*, having three digits on the right pincer or great claw. The supernumerary digit, which is fully two-thirds the size of the normal one, springs from the inner side of the base of the inner movable finger, and is sharply toothed on both sides, and directly opposable to the outer finger. The normal digit is fully developed and curves outwards from the supernumerary one at a wide angle, the distance between them being fully three-quarters of an inch at the points. They move together, and permit an opening of about half an inch between the supernumerary and the normal outer digit, so that little or no inconvenience would be caused to the animal during life. This specimen was caught by fishermen in the neighbourhood of Cumbrae, and was given to a Millport gentleman, Mr. Liddle, who kindly handed it over to the Museum.

ALEXANDER GRAY.

Millport Marine Biological Station, March 6.

SCIENTIFIC EXPERTS AND PATENT CASES.

WE have often had occasion to point out the many disadvantages which are connected with the present system of obtaining and using scientific evidence in courts of law. The disadvantage which chiefly concerns us is that science and men of science are at times thereby drawn into and through mud of a most objectionable quality; but there are many others.

We are glad to see that the matter has again been brought to the front, and this time by the Lord Chancellor himself, and that alterations in the present mode of procedure are being discussed.

We content ourselves this week by reproducing the following leading article in Wednesday's *Times*:—

In the recent sittings of the Law Courts nothing has been more remarkable than the large number of patent actions. Certain inventions have been veritable gold mines to patent lawyers, agents and experts. The bicycle is scarcely more familiar in the streets and highways than in the Courts. We could name patentees who are never out of litigation to protect their menaced rights; certain lamps, gas burners, and explosives are always "going to the Lords." A very substantial part of judicial time is taken up in examining the rival claims of inventors, and they are likely to ask for more. The history of science is constantly illustrating the fact that the same ideas are in many minds at the same time, that often it is an accident whether A or B first propounds his suggestions, and that the priority of one over the other may be a matter of a few months or even days. That is a partial explanation of the multitude of disputes as to bicycle tires, bicycle saddles, metal rims, chains, and gear of all sorts. A further explanation is to be found in the profits derivable from patents as to articles used by hundreds of thousands. Sometimes the Courts are called upon to decide between two independent inventors. Just as often the fight is between one who has an honest claim and another who wishes to levy blackmail or to be bought out. The mode of determining such actions is far from satisfactory. The Lord Chancellor, in a case in the House of Lords which we reported the other day, gave expression to a widespread opinion on this point. The case turned on five or six lines in a specification relating to the tires of bicycles; but it occupied inordinate time both in the Court below and in the Court of Appeal. "Having regard to the extravagant and extraordinary consumption of time which was involved in the determination of this case," said the Lord Chancellor, "witnesses of great eminence being called upon both sides and evidence given which amounts in the book which I hold in my hand to 500 printed quarto pages, it is no wonder that, if a case so simple in its character is so protracted, there is what is called a 'block' in the Courts of law." So serious is the state of things that the Lord Chancellor intimated that it might be necessary to hand over to a special tribunal the trial of cases for which the ordinary procedure seemed inapt. A well-informed correspondent, Mr. W. L. Wise, in a letter which we publish to-day, expresses much the same opinion in even stronger terms. "The present state of things virtually amounts to a denial of justice to all but those having the command of large sums of money." This is an old complaint. Years ago the late Master of the Rolls said, "There is something catching in patent cases, which is that it makes everybody argue and ask questions to an interminable extent. A patent case, with no more difficult question to try than any other case, instead of lasting six hours, is invariably made to last six days, if not twelve. I am sure there ought to be some remedy for it." In Ehrlich *v.* Ihlee" the Court of Appeal took occasion to complain of the "frightful mischief" caused by the prolixity of the proceedings in patent actions. Mr. Wise suggests a remedy. He points out that the Comptroller-General of Patents or his deputy determines questions not unlike the questions of infringement which come before the Courts; and he trusts that, if the staff of the Patent Office were strengthened, a tribunal more economical, expeditious, and not less fit than the present would be found. An appeal lies to the law officers; and it is a recommendation to the suggested system, in the eyes of our correspondent, that at all stages patent agents may appear for the parties.

We have our doubts about the efficacy or success of this recommendation, though certainly not on the ground that patent agents, whom the Legislature has very properly recognised, would have a larger field than is now theirs. We should be glad to see them invested with more privileges, and corresponding responsibilities when they proved ignorant and careless. But such a tribunal would not satisfy patentees, who are the most pugnacious and persevering of litigants. Beaten in one Court, they will resort to another; if they at last acquiesce in the decision of the House of Lords, it is only because there is no tribunal above it. Such are the uncertainties necessarily attending many of the disputes, and, above all, such are the rewards that come with success in patent actions, that every weapon is, and always will be, used in the fight. It is not to be expected that, to take two examples at random, the parties to the litigation before Mr. Justice Wills in 1896 and 1897 in "The Incandescent Gas Light Company *v.* the De Mare Incandescent Gas Light System" and "The Pneumatic Tyre Company *v.* the Ixion Pneumatic Tyre Company" would be content with the decision of a few officials of the Patent Office. In the great majority of the cases referred to by the Lord Chancellor and by our correspondent much money is at stake; and the parties will spare no expense to gain their point.

A more plausible suggestion is that the evidence should not be left, as it now is, solely to the discretion of the parties; that the Judge should nominate some experts—if possible one in whom all have confidence—to report on the invention and the question of novelty, validity, or infringement; and that he should be guided by the report unless it was shown to be erroneous. This would prevent the competition, so common and so ruinous to poor litigants, in the production of expert evidence. It is no small recommendation of this suggestion that under other systems of law it is adopted and is found to answer. There is, however, some force in one criticism—Where, in many cases, is a truly impartial expert to be found? If the question is one of great importance, a scientific witness of eminence has probably in his writings or in some discussion committed himself, directly or indirectly, to an opinion on one or more of the points involved. To take an actual instance, it would have been difficult in the recent litigation between the Maxim-Nordenfelt Company and Sir William Anderson to have found a chemist whose report on the properties of the explosives under consideration would have been accepted as *prima facie* valid. Good might come of a special tribunal framed on the lines of the Commercial Court. But sometimes what is imperatively needed is the unbiased opinion of an intelligent outsider with no theories about physics. One point of delicacy is rarely touched by the critics of the existing system. It must be present to them all. In some professions a traditional sense of honour prevails to which all must conform, or appear to do so, and which prevents open and flagrant deviations from rectitude. Among doctors, for example, there are black sheep; but they keep well out of sight. It is notorious that, even in cases in which life and death are at stake, or when there happens to be a temptation to speak loosely, it is rare to find a doctor giving evidence in favour of theories which his brethren would scout as manifestly absurd. Could as much be said of the testimony of scientific experts in patent actions? There may be countries in which such witnesses never overstate the case and never sell their opinion. Ours is not one of them. Many scientific witnesses who ought to know better have acquired a very bad habit; they have come to regard themselves as advocates—in the witness-box. It seems a poor palliation of a real evil to press on scientific experts—some do not need that counsel—a loftier notion of their function than befogging the Judge or finding more or less plausible reasons for what they know to be untenable and absurd.

PHOTOGRAPHIC SURVEYING.

FIFTY years ago or more, M. Beautemps Beaupré successfully employed a process which greatly facilitated the work of surveying, and which in its modern developments is likely to supersede the tedious work of measurement in the field. Where the greatest accuracy was not required, the method recommended itself on account of its great practical utility, enabling contoured maps to be produced without the labour of heavy calculations. M. Beaupré availed himself of the principle of the camera lucida, and by its aid sketched the panorama about him from two ends of a measured base line. In a paper recently communicated by Prof. E. J. Mills to the Institution of Engineers and Shipbuilders in Scotland, it is contended that the best work is still done when this principle is utilised. From two views taken at a known distance from each other, however procured, one is able to plot a map with a fair amount of accuracy, and knowing the correct relative distances of the objects their vertical height can be deduced. No doubt there were difficulties in the application of the method. Any one who has attempted to draw a picture of a distant object by means of Wollaston's invention knows that the result is apt to be a little disappointing, though successive improvements in the mechanism have removed many of the effects arising from parallax, which interfered with correct delineation in the early days when the instrument was first used. But the process still remains long and tedious, and it was inevitable that the introduction of photography with its rapid and accurate results, should be welcomed as likely to banish the slow methods of hand drawing in the initial stages of the work.

To obtain a photograph which should be free from optical distortion, and to which the laws of geometrical perspective could be applied without any correction, has not been an easy task. But now it may be said that we do possess lenses which will cover an angular field of about 60° without measurable distortion, and give uniform definition all over the plate. Enlargements and printing from the original negatives doubtless still present some difficulties. Prof. Mills, we notice, recommends that the prints should be made on bromide paper, and developed with amidol. Shrinkage and distortion of the paper will, it is asserted, be prevented, when soaked in a two per cent. solution of formalin, and dried at a gentle heat. Other authorities, however, distrust paper altogether, and prefer to use a bromide emulsion on opaque or translucent plates of flat glass as likely to give less error. But the possession of accurate optical arrangements, combined with exact manuipulation of the photographic result, suggests many new applications to which the camera can be profitably applied, and the surveyor now finds himself equipped with an instrument of scientific precision, in which are combined the main features of a theodolite and a level, and which replaces the plane table and its accessories.

In the earliest form of surveying camera or photogrammeter, to give it a polysyllabic title, the instrument consisted of little more than an ordinary bellows camera, set on a horizontal circle, and moving about a vertical axis. The distance between the plate and the lens was fixed, and the camera could be levelled by means of screws in the head of a tripod in much the same way that a theodolite is adjusted. In the subsequent development and increased effectiveness that have been added to this surveying instrument, two names stand out prominently, that of Colonel Laussedat, the present Directeur of the Conservatoire des Arts et Metiers, Paris; and in this country that of Mr. Bridges Lee. In the French form, the camera is placed on the top of a stand carrying a transit theodolite, and the disposition of the several parts is arranged to ensure stability and symmetry about a vertical axis, while each part of the instrument can be used separately. In the English form, Mr. Bridges Lee has wisely determined that while each photograph should offer a correct perspective view of the country it represents, it should also carry on its face the information necessary for the correct interpretation of the picture, and the subsequent construction of a map. When passing through countries where roads are scarce and travelling difficult, notebooks are apt to be lost; but without more words, every one must appreciate the arrangement by which the "constants of reduction" are made as permanent as the picture to which they refer.

The general principles on which the Bridges Lee camera has been constructed, and the objects sought to be attained, have already been briefly explained in these columns (vol. li. p. 191). Its present form has been adopted because experiment has proved the necessity of great nicety of mechanical adjustment to obtain the best results. To ensure the necessary lightness and rigidity, the camera box is made of aluminium. The direction in which the instrument is pointed can be read off an azimuthal circle, graduated to minutes, on which the camera turns. A level on the top of the box ensures the horizontality of the instrument, and when this adjustment has been made, a telescope, also securely attached to the top of the camera, will move in a vertical plane through a sufficient range of angle for all ordinary terrestrial work. The angle through which the telescope can be moved in altitude is also read to minutes. This supplies the observer with a theodolite, and its position is so arranged with reference to the other parts of the instrument, that the line of collimation and the vertical wire of the theodolite are in the same plane with that which bisects the photographic lens. In this same vertical plane, a "wire" is fixed to the frame of the camera, cutting the optic axis of the lens at right angles, and consequently marks on the photograph the median vertical plane of the instrument. Another wire, also through the optic axis at right angles to this, will mark the horizon of the instrument on the picture, and the intersection of the two wires will give the "principal point" of the perspective. Inside the camera is placed a magnetic compass, and the scale being transparent, it is printed on the picture. The axis of rotation of this compass is in the same plane as the axis of collimation of the theodolite, and of the vertical wire. The distance between the scale of the compass and the vertical wire is kept constant by a device which works automatically when the camera is in use, and since this distance very slightly exceeds the radius of the compass, the wire can be used as a pointer to read the scale. One very important addition to the usefulness of the instrument is the insertion of a scale of angular distance, photographically prepared by the same lens as that fitted in the instrument when complete for surveying purposes. The scale is so attached to the frame, that it is photographed on every picture taken, and by its aid one can easily read off the angular distances of any point in the picture right or left of the median vertical plane.

A method of surveying in which the necessary observations are easily and rapidly collected, or are implicitly contained in a series of photographic views, has the promise of a large future. In travelling over unsettled districts, where it is impossible to remain for any length of time on a particular spot, the photographic method seems likely to supersede all others. Indeed no other method seems possible. Moreover, a photograph contains an amount of detailed information concerning the country photographed, which it is quite impossible to gather from notes of observations and sketches, although much time may be spent in making these additions as carefully as possible. In this connection, one might call attention to the beautiful mountain maps which have been prepared for the German and Austrian Alpine Club

Here the work is based on the original ordnance survey maps, and the topographical details filled in from photography. These maps represent one of the most successful applications of photographic surveying. Again, in preliminary experimental surveys for irrigation purposes, or for deciding on the best route for a proposed railway, the camera, properly controlled, possesses many advantages over ordinary surveying instruments. In such cases it is often excessively difficult to determine beforehand how much plotting will be necessary to secure the object in view. The district may have to be re-visited over and over again to supply the requisite details, all of which may prove useless in the end. But with the photographic pictures secured by a camera, the plan may be plotted so far only as required, and if additional information be needed, the photographs can be made to give all the detail wanted without going again to the field. Irrigation surveys for agricultural purposes have been effected in the North-West Provinces with complete success by the photographic method, and are likely to be still further extended. Prof. Mills tried to apply the method to the determination of the content of a ship in dock by constructing a model of the vessel in clay, the necessary dimensions for which were to be taken from measured photographs. When the amount of clay in the model, and the scale of the photograph from which the necessary measurements have been taken are both known, the capacity of the ship is at once determined. In this particular instance, it is true, the method failed, owing to the impossibility of selecting suitable stations for the photographs amid the crowded machinery of a busy ship-building yard. But the attempt shows the wide applicability of the method and the extent of the field open to the intelligent use of photographic appliances.

But its greatest triumphs are, of course, to be seen when the method is continuously applied over a large area. One of the most successful operators is Mr. E. Deville, the Surveyor General of Dominion Lands, who has carried his investigations over the difficult passes of the Rocky Mountains, and surveyed the country up to the United States boundary of the Alaska territory. No less than 14,000 square miles of this inhospitable country were surveyed in the years 1893-94. The proper administration of the country, he tells us, required a tolerably accurate map, and means had to be found to execute it rapidly, and at a moderate cost. The ordinary methods of topographical surveying were too slow and expensive for the purpose; rapid surveys, based on triangulations, and sketches were tried and proved ineffectual; then photography was resorted to, with the result just mentioned. The same authority, as was natural to one in his official position, has made a very careful comparison of the relative expense of a survey made with the plane table and one with the camera: all such comparisons are liable to be modified by the climatic conditions of the country, and the amount of detailed plotting required. In the climate of the Rocky Mountains, Mr. Deville estimates that on one half of the number of days in a season, no work can be done with a camera, owing to smoke, fog, rain and snow storms. But quite as great a loss of time is experienced with the plane table, added to which the apparatus is more weighty, requiring more porterage, and therefore additional expense in removal. But neglecting these and some other slight advantages which are on the side of photography, he finds that the plane table survey is three times (rigorously as 164 : 56) more expensive than that accomplished by the camera. This is a real practical advantage which is immediately appreciated, and on several grounds, not taken into Mr. Deville's estimate, such as the possibility of reducing the number of highly-trained assistants, it would seem that the difference of expenditure has not been over-estimated. There is no sacrifice of accuracy to secure this economy; the great improvement consists in the substitution of the methods of photography—methods, which proving highly popular, must tend to displace more and more the use of the plane table.

BALNIBARBIAN GLUMTRAP RHYME.

(Repeated by the children in the nurseries of Balnibarbi.)[1]

DISTANT scintillating star,
Shall I tell you what you are?
Nay, for I can merely know
What you were some years ago.

For, the rays that reach me here
May have left your photosphere
Ere the fight of Waterloo—
Ere the pterodactyl flew!

Many stars have passed away
Since your æther-shaking ray
On its lengthy journey sped—
So that you, perhaps, are dead!

Smashed in some tremendous war
With another mighty star—
You and all your planets just
Scattered into cosmic dust!

Strange, if you have vanished quite,
That we still behold your light,
Playing for so long a time
Some celestial pantomime!

But, supposing all is well,
What you're made of, can I tell?
Yes, 'twill be an easy task
If my spectroscope I ask.

There—your spectrum now is spread
Down from ultra-blue to red,
Crossed by dark metallic lines,
Of your cooler layer the signs.

Hence among the starry spheres
You've arrived at middle years—
You are fairly old and ripe,
Of our solid solar type.

Ah, your sodium line is seen
Strongly shifted towards the green.
Hence you are approaching me
With a huge velocity!

But, if some celestial woe
Overtook you long ago,
And to swift destruction hurled
Life on every living world,

Did there in the fiery tide
Perish much of pomp and pride—
Many emperors and kings,
Going to do awful things?

Mighty schemes of mighty czars—
Mighty armies, glorious wars!
From the Nebula they may
Rise to curse a world some day!

G. M. MINCHIN.

---

[1] Balnibarbi is one of the countries visited by Gulliver; the "Glumtrap" is the Balnibarbian equivalent of the English nursery; and the babies of Balnibarbi are brought up on strictly scientific principles—as is evidenced by their knowledge in these verses.

NOTES.

THE preliminary circular for the jubilee meeting of the American Association for the Advancement of Science to be held at Boston, August 22–27, has just been issued. Prof. Frederick W. Putnam, the president-elect, repeats the assurance given to the nominating committee at the last meeting, that this second Boston meeting, held on the fiftieth anniversary of the foundation of the Association, "gives promise of being the most important scientific gathering ever held in the United States." A special effort will be made to increase the membership, in the hope that at least one thousand new members will be added. The meetings will be held at the rooms of the Massachusetts Institute of Technology, and of the Boston Society of Natural History, occupying three closely adjoining buildings. The Association will be for one day a guest of Harvard University, and for another of the Essex Institute of Salem; the latter being the place of the museum of the Association, and its permanent office. A larger number than usual of the affiliated societies will meet in connection with the Association, including the American Forestry Association, the American Geological Society, the American Chemical Society, the Society of Economic Entomologists, the Society for the Promotion of Engineering Education, the Society for the Promotion of Agricultural Science, the American Mathematical Society, and several more. After the meeting excursions will be made to the White Mountains and to Cape Cod. The local committee has been fully organised under the honorary presidency of Governor Roger Wolcott. The honorary vice-presidents include the presidents of fourteen colleges and universities, besides many other prominent gentlemen. The local secretary is Prof. H. W. Tyler, of the Massachusetts Institute of Technology, 491 Boylston Street, Boston; and the general committee is a large and representative one, composed of the foremost citizens. The chairmen of the other committees are: Finance, the honorary treasurer, Colonel Henry L. Higginson; Reception, Dr. J. R. Chadwick; Rooms for meeting, Prof. Charles R. Cross; Invitations to foreign guests, Dr. Henry P. Bowditch; Excursions, General Francis H. Appleton; Cambridge committee, Prof. Charles W. Eliot, of Harvard University; Salem committee, Hon. Robert S. Rantoul, president of the Essex Institute; Executive committee, Prof. W. T. Sedgwick. An unusual feature is the committee for the reception of foreign guests. The circular explains that special efforts will be made to secure the presence of many eminent men of science from abroad.

A BUST of the late Prof. P. Schützenberger, the distinguished chemist, was unveiled at the Paris École de physique et de chimie industrielles on April 3. Prof. Schützenberger was the founder and first director of the school, and the bust is a testimony of the affection in which his memory is held by old students.

OLD students and admirers of Dr. W. K. Brooks, professor of zoology in the Johns Hopkins University, Baltimore, presented him with his portrait, painted by Mr. T. C. Corner, upon the occasion of the fiftieth anniversary of his birth on March 25. Many leading zoologists of the United States took part in this expression of esteem for Prof. Brooks.

THE autumn congress of the Sanitary Institute will be held this year in Birmingham, under the presidency of Sir Joseph Fayrer, Bart., K.C.S.I., F.R.S., commencing on September 27.

THE annual exposition organised by the Société Français de Physique will open to-day with a visit to the works of the Paris Compressed Air Company. On Friday and Saturday evening a large collection of apparatus used in recent physical investigations will be on view in the rooms of the Society; and on Saturday afternoon short addresses will be delivered by MM. Ducretet, Morin, and Hurmuzescu.

THE Liverpool Marine Biology Committee's Easter party, now at the Port Erin Biological Station, includes Mr. Isaac C. Thompson, Mr. Frank J. Cole, Mr. R. A. Dawson, Mr. H. C. Chadwick, Prof. Herdman, and several students from University College, Liverpool. Prof. Boyce and others are expected later in April. The Lancashire Sea Fisheries steamer is also at Port Erin, and several dredging and trawling expeditions are taking place. Spawn of several fishes has been obtained, and fertilised, and is now developing in the tanks. Under the care of Mr. Chadwick, Curator of the Station, the aquarium is in a flourishing condition, and contains a number of interesting animals, some of which are spawning. A recent addition to the laboratory accommodation at the Station has been completed, which gives five additional work windows for students, so that there is now plenty of room for other workers.

DR. H. M. FERNANDO will probably be the director of the Bacteriological Institute to be opened in Colombo shortly. The final plans for the building have been completed, and the work will be taken in hand at once. It is expected that the Institute will be opened by the beginning of next year.

WE learn from *Science* that the United States Senate has passed a Bill for the protection of song birds, providing that the importation into the United States of birds, feathers, or parts of birds for ornamental purposes be prohibited, and prohibiting the transportation or sale of such articles in any territory of the United States or in the District of Columbia.

THE vanguard of exploring expeditions for the season is that of Dr. Carl Lumholtz and Dr. Hrdlicka, who left the American Museum of Natural History a few days ago in search of anthropological specimens for the museum. This will be followed in a few weeks by an expedition to the North-west, undertaken also for anthropological research, by Dr. Laufer, Mr. Gerard Fowke, Mr. R. Dixon, and Mr. H. Smith.

THE most violent earthquake in California since 1872 was felt on Thursday night, March 31. The shock was felt only in Northern California. The direction of vibrations was from east to west; and they were very heavy in a small area. The seismograph showed the duration of the earthquake to have been between thirty and forty seconds at the University of California, Berkeley. Damage was done to buildings at San Francisco and Vallejo; but no loss of life has been reported.

THE death of Prof. Salomon Stricker, the distinguished professor of experimental and general pathology in the University of Vienna, at the age of sixty-five, is announced in the *British Medical Journal*. Only a week or two ago Prof. Stricker celebrated the twenty-fifth anniversary of his appointment as professor, and the occasion was celebrated by presenting him with a *Festschrift* entitled "Thirty Years of Experimental Pathology," the list of contributors including the names of E. Albert, A. Spina, G. Gaertner, Dr. E. Klein, and many other pathologists and histologists of note.

M. DE FONVIELLE writes:—The 1898 session of the international balloon scientific conference was held in Strasburg with great success. A large number of resolutions were adopted referring to the ascent of free balloons carrying registering apparatus, and balloons with meteorological and photographic instruments. The conference passed a vote in favour of the extension of kite experiments with recording apparatus or kite-balloons to the international meteorological stations, in order to procure better information on prevailing meteorological influences. It was resolved that an international experiment should take place at the beginning of June. In addition to the Paris, Strasburg, Berlin, and Petersburg stations, two new stations will be established in Vienna at the expense of the Minister of War, and in Brussels. The expenses will be supported by the Belgian-Deutsch Society of Astronomy, which sent to Strasburg, as their representative, M. Fievre, one of their secretaries. The next meeting will take place in Paris in 1900, on the occasion of the forthcoming exposition. Among the members present at the recent meeting were the director of the Russian Meteorological Service; Commander Kovanko, director of the Russian Aeronautical Service; Herr Assmann and Dr. Berson, of the Berlin Meteorological Institute; M. Cailletet, member of the French Academy of Sciences; M. Teisserenc de Bort; Mr. Rotch, director of the Blue Hill Observatory in Pennsylvania; M. Besançon; and Prof. Heim, the Swiss geologist, professor in the Zürich Polytechnicum.

We regret to see that Mr. James I'Anson, an occasional contributor to our correspondence columns, died a few days ago. From the *Engineer* we learn that Mr. I'Anson was born at Gateshead in 1845, and came of an old North-country family. Soon after leaving school he commenced his apprenticeship as a mechanical engineer, and in 1866 he entered the engineering works of the late firm of Charles I'Anson and Co., becoming subsequently a partner. Some time after he became managing partner, a position which he held until his retirement in 1885. Mr. I'Anson was for many years a Fellow of the Geological Society, and he also sat upon the Council of the Mineralogical Society of Great Britain and Ireland. He was a member of the Iron and Steel Institute and of the North of England Institute of Mining and Mechanical Engineers, to whose proceedings he contributed papers, as also to those of the Cleveland Institute of Engineers, the Mineralogical Society, and the British Archæological Association.

Among the problems interesting to the physicist and mathematician which are discussed at the meetings of the Institution of Naval Architects, few open up such a wide field of inquiry as those which form the subject of Prof. H. S. Hele-Shaw's paper, entitled "Investigation of the nature of surface-resistance of water, and of stream-line motion under certain experimental conditions," read before the recent meeting of the Institution. In a previous paper, read last July, the author showed how the flow of water in two dimensions past obstacles of various cylindrical and prismatic forms could be investigated experimentally by the use of water containing a quantity of air flowing between two parallel plates of glass, the air rendering the water turbulent where the motion was most rapid. The photographs, which Prof. Hele-Shaw reproduces, show in every case a clear line round the boundary of the solid, indicating a thin film in which shearing motion takes place past the surface, while outside this comparatively calm region streaks of air are noticeable. The figures, moreover, show the presence of regions of dead water behind obstacles with blunt edges, fully confirming the view that to minimise resistance a solid must be made to taper at its stern end rather than at its bow end. In the present paper diagrams are given showing the variations in thickness of the entrained film according to the smoothness or roughness of the surface of the solid, the addition of soap to the water, and other circumstances. A second field of experiment has been developed by the use of thin films of water flowing between parallel plates, in which the stream-lines are shown by the introduction of coloured bands. Unless the film be very thin (about 0·5 mm.), the lines of colour become blurred, especially after flowing round an obstacle. The most remarkable result is the coincidence between the stream-lines in these experiments, where we are probably dealing with a case of laminated motion of a viscous liquid largely affected by the bounding plates of glass, and the corresponding stream-lines calculated mathematically for the irrotational motion of a perfect liquid in two dimensions. It has been one of the great objections to the mathematical theory of fluid motion that the conditions imposed by the mathematician differ considerably from those occurring in practice. Prof. Hele-Shaw's investigations, however, bid fair to bring hydrodynamics within the range of experimental sciences, besides fulfilling the object for which they were primarily undertaken—that of teaching naval architects how to minimise the surface-resistance on ships.

At the meeting of the Institution of Civil Engineers on April 5, Mr. A. H. Preece gave an account of the present state of electricity supply in London. There are now in London eleven important companies and five vestries supplying electricity, and three other companies and three vestries are taking steps to start works. Five companies and three vestries supply the alternating current, and the remainder use direct-current systems. The direct-current systems are divisible into two classes—the high-pressure and the low-pressure. In the former, rotary transformers are used to reduce the high pressure to a low pressure, while the latter produces and distributes electricity at the same pressure at which it is supplied to consumers. The direct-current systems are applicable to compact areas, and, with the use of high pressure, to scattered or isolated compact areas. The chief advantages of the direct-current system are the possibility of using storage-batteries, which can not be employed with the alternating-current systems, greater efficiency in distribution, and greater adaptability to motive power. The favourite methods of distributing electricity are to transmit current at a high pressure in heavily-insulated cables in iron pipes, and current at a low pressure in insulated cable in stoneware conduits, or in cables heavily armoured and laid direct in the ground. Rubber is now little used, paper and jute, impregnated with insulating compounds, having been extensively adopted. The electric supply industry is rapidly growing, and no less than 40,000 h.p. is now being installed in London in order to meet the demand for electricity in the immediate future.

The *Times* correspondent at Cairo makes the important announcement that M. Loret has discovered and opened at Thebes the tomb of Amenophis II, a king of the XVIII. dynasty, who reigned some 1500 years B.C. The tomb contains the mummies of Amenophis and of seven other kings, besides two mummies bearing no name, and four bodies which, though they have not been embalmed, are all in a complete state of preservation, with the features perfect. The hair upon each of these bodies is luxuriant, and the features are said to resemble to a marked degree those of the fellaheen of the present day. M. Loret's find is amongst the most interesting ever made in Egypt.

The Central Physical Observatory of St. Petersburg has published an interesting pamphlet showing, for the whole of the Russian Empire, the absolute maximum and minimum temperatures at about 230 stations, accompanied by three maps, illustrating the above elements, and the ranges of temperature. The observations at some of the stations extend over a long series of years, *e.g.* St. Petersburg, 142 years; Moscow, 90 years; and Archangel, 80 years. The most remarkable temperatures and ranges are recorded in the Province of Yakutsk, in Siberia:—Verkoiansk, − 90° F. with a range of 182°·7; Markinskoe, − 85°·0, range 185°·2; Yakutsk, − 84°·1, range 185°·7. All these extreme minima occurred in the month of February, and the stations being a considerable distance apart, testify to their accuracy and to the great rigour of the winter of that locality. The work has been compiled by Mr. A. Varnek; but the text being in Russian only, detracts somewhat from its general usefulness.

The sources of commercial india-rubber form the subject of two Cantor Lectures to be delivered at the Society of Arts on Monday, April 18 and 25, by Dr. D. Morris, C.M.G.

An instructive article upon processes of alkali manufacture, with special reference to the works of Messrs. Brunner, Mond, and Co., appeared in yesterday's *Times*.

We have received from Mr. C. Leeson Prince the summary for the year 1897 of meteorological records which he keeps at his observatory on Crowborough Hill, Sussex. Perhaps the most important event of the year occurred on May 30, when, as he says, "a more memorable thunderstorm passed over a portion of this country than has happened within living memory." This storm, from all accounts, did not actually occur at Crowborough Hill; but from its elevated position the progress of the storm, though twenty miles distant, could be watched for a considerable time. Mr. Prince gives a reproduction of some of the hailstones which had previously fallen at Seaford during the same storm. These were found to be still larger, as will be seen by the accompanying illustration showing the hailstones in their natural size.

[*From a Photograph by Wynter, Seaford.*

A reproduction (natural size) of some hailstones which fell at Seaford during the thunder-storm of May 30, 1897.

We have received from Dr. T. Homén, of the University of Helsingfors, a laborious investigation, entitled "Der tägliche Wärmeumsatz im Boden und die Wärmestrahlung zwischen Himmel und Erde," being a continuation of a work published in 1894, in which the author dealt more particularly with earth temperature, evaporation and dew. In the present publication Dr. Homén attempts the determination of the amount of heat which enters various kinds of soil during the day, and the amount given up by radiation during the night. We are unable to give an adequate account here of the various interesting results contained in a quarto volume of about 150 pages, but we may mention that the experiments appear to have been carried out with great care. The thermometers were placed at various depths below and heights above the ground, and show clearly the effect of the soil upon the air temperature and humidity during the various hours of the day and night. The conditions of humidity were found to be very different between the level of the ground and the height of about 33 feet (at which the highest thermometers were placed), being less in the night and greater in the day in the lower than in the upper strata of air.

The Rev. W. Sidgreaves, in his report of the Stonyhurst College Observatory for 1897, gives us the results of the meteorological and magnetical observations made during the past year, with notes and comments. In addition to these observations, which have been carried out with the utmost regularity, other branches of work have been followed. Thus preparation was made for photographing trails of the November meteors, five cameras having been mounted round the object-glass end of the equatorial, but the weather proved too unfavourable. Again, 174 drawings of solar spots and faculæ were made during the twelve months, and enlarged drawings of spots near the solar limb were undertaken to obtain evidence about the level of the umbra. As regards stellar spectroscopy 240 plates were exposed, the work in hand being directed to the sequence of spectrum differences of the yellow and red stars, from those of the solar type to the type of α Herculis. An appendix to this report contains the results of meteorological observations for 1897, made at St. Ignatius' College, Malta, by the Rev. J. F. Dobson.

Science states that in addition to the plans of the Geological Survey for explorations in Alaska, the Treasury Department are about starting five or six expeditions to explore the Yukon river, Copper river, and other water routes of the Territory, the United States Congress having granted 100,000 dollars for the purpose.

Scientific facts are presented to the public freely and attractively in three lectures which have been arranged at the Whitechapel Free Public Library and Museum. On Tuesday Prof. Hobday lectured on "The Horse and Dog and their relations and friends." On Tuesday, May 10, Prof. W. F. R. Weldon, F.R.S., will discourse upon "Butterflies"; and on June 7, Prof. Marshall Ward, F.R.S., will give an address upon "A Piece of Wood." Admission to the lectures is free by ticket, which can be obtained in the Museum and Library.

Appendix II. for 1898 of the *Kew Bulletin* is entirely occupied with a list of New Garden Plants of the year 1897, including also the most noteworthy of those which have been re-introduced after having been lost from cultivation. In addition to species and botanical varieties, all hybrids, whether introduced or of garden origin, with botanical names, and described for the first time in 1897, are included.

Messrs. J. and A. Churchill announce that they will publish in a few days a new work on "The Blood: how to examine and diagnose its diseases," by Dr. Alfred C. Coles, illustrated with six coloured plates. They will also issue a fifth edition of "A Manual of Dental Anatomy, Human and Comparative," by Mr. Charles S. Tomes, F.R.S., with many new illustrations. The part dealing with comparative odontology has been expanded to meet the requirements of students of biology.

The additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (*Macacus cynomolgus*) from India, presented by Mrs. Grace Currie; a White-tailed Sea Eagle (*Haliatus albicilla*) from the Liautung Peninsula, China, presented by Mr. J. W. Carrell; ten Californian Quails (*Callipepla californica*) from California, presented by Captain Thos. Yardley Powles; a Common Viper (*Vepera berus*). British, presented by Mr. R. Tucker; an Egyptian Jerboa (*Dipus ægyptius*), four Egyptian Ichneumons (*Herpestes ichneumon*), six Gulls (*Larus*, sp. inc.), a Common Kestrel (*Tinnunculus alaudarius*) from Egypt, a Leopard (*Felis pardus*) from West Africa, a Reticulated Python (*Python reticulatus*) from Malacca, deposited; a Chimpanzee (*Anthropopithecus troglodytes*, ♂) from West Africa, a Rosy-billed Duck (*Metopiana peposaca*, ♀) from South America, purchased.

OUR ASTRONOMICAL COLUMN.

The Doubling of the Canals on Mars.—The origin of the doubling of the canals visible on the surface of the planet Mars has again come to the front, and this time M. Antoniadi has put forward an explanation. His suggestion is that the doubling is only a phenomenon caused probably by the eye of the observer; in fact, it is the result of slight focussing errors when observing these markings. A full account of this curious cause of error is contributed to *Cosmos* (No. 687) by M. Th. Moreux, and M. Antoniadi himself gives a complete summary of his suggestion in the *Bulletin de la Société Astronomique de France* for April. According to the latter, a thin line, when gradually put slightly out of focus, becomes slowly double, the inner parts of which are blurred; in fact, a regular germination is observed. In addition to this, he finds that if several lines be made to cross at a point, all of these do not become double, but only certain of them. Not only do straight markings, but round and elongated spots become alike doubled. At the end of his paper, after remarking on the curious phenomenon of canals, as actually observed, becoming double in the course of a few hours, he says:—

"Ainsi, si Mars est couvert de 'canaux,' la vision imparfaite devra *dédoubler ces lignes*. Pareille vision indistincte peut provenir, ainsi que nous venons de le voir: 1° d'une minime erreur de mise au point; 2° d'oscillations diplopiques (fatigue) de l'œil. Voila ce qui doit fatalement arriver, el ce qui arrive en réalité."

M. Camille Flammarion tells us in the same journal that M. Adolphe de Boe, of Anvers, in the year 1891 suggested, in a letter to him, that this doubling might be the result of secondary images which, under certain conditions, might be formed in the eye. M. Flammarion is, however, no great believer in this idea, as it does not seem to sufficiently explain all the phenomena of doubling, germination, &c., which have been observed on the surface of this interesting planet, although the arguments brought forward reproduce very ingeniously the greater part of the observations. With him we echo the sentiment of wishing to know what M. Schiaparelli has to say on the subject.

Comet Perrine.—The latest elements and ephemeris of this comet have been calculated by Prof. H. Kreutz, who gives the results in No. 4 *Circular* recently distributed.

The elements computed from the observations of March 19, 23, 27 and 31, differ slightly from those we have previously given, being:—

$$T = 1898 \text{ March } 17{\cdot}37558 \text{ Berlin M.T.}$$

$$\left.\begin{array}{rl} \omega = & 47^\circ\ 34'\ 12''{\cdot}1 \\ \Omega = & 262\ \ 33\ \ 59{\cdot}6 \\ i = & 72\ \ 27\ \ 48{\cdot}1 \end{array}\right\} 1898{\cdot}0$$

$$\log q = 0{\cdot}040842$$

The ephemeris for the ensuing week is as follows:—

1898.	R.A.			Dec.	log r	log Δ	Br.
	h.	m.	s.				
April 14	23	7	15	+40 47·7	0·0757	0·2233	0·77
15		12	13	41 32·9			
16		17	15	42 16·9			
17		22	20	42 59·7			
18		27	27	43 41·3	0·0851	0·2330	0·71
19		32	37	44 21·6			
20		37	49	45 0·6			
21		43	3	45 38·4			
22	23	48	19	+46 15·0	0·0953	0·2438	0·64

It will be noticed that the brightness of this comet is gradually decreasing, and by the end of the month it will be about half that at the time of discovery.

The April Lyrids.—As pointed out in this column on March 31 (p. 519), the April shower of meteors is due on 19–20 of this month. The conditions for viewing these bodies if they should be numerous will be very favourable, as the moon will be absent. As Mr. Denning tells us, the periodical maxima of this stream of Lyrids has a computed time of revolution of 415 years, a brilliant display having occurred on April 20 in the year 1803. The radiant point is 270° + 32°.

The Meudon Observatory.—Prof. Janssen is evidently bringing together a very strong force at the Astro-Physical Observatory at Meudon. We hear now that, in addition to the other experienced astronomers who are working there, M. Deslandres has been transferred from Paris, and will in future continue his valuable spectroscopic researches at Meudon.

PREHISTORIC RUINS OF HONDURAS AND YUCATAN.

In 1891 the Directors of the Peabody Museum secured from the Government of Honduras (through the liberality of Mr. C. Bowditch, of Boston) the right to explore the ruins of Copan, and to take away half of the objects found in the excavations, during a period of ten years. The preliminary report of the exploration,[1] now published by the Directors of the Museum, gives the result of the first two years' work, and is accompanied by a plan and many excellent photographic plates.

All those interested in American archæology must be for ever grateful to the Committee directing the expedition for one instruction given to the explorers; it was to the effect that a wall should be built round the principal group of ruined structures and carved monoliths, so as to save them, if possible, from further destruction. This work has now been most satisfactorily carried out, and the ruins, which were always safe from approach on the river face, are now enclosed on the land side by a substantial stone wall nearly one mile in length.

---

[1] *Memoirs of the Peabody Museum, &c.* Vol. i. No. 1: "Prehistoric Ruins of Copan, Honduras." "A Preliminary Report of the Explorations by the Museum, 1891–95."

Examination and excavation have thrown no light on the age of the buildings; in fact, the further examination has only complicated the problem, as clearer proofs are forthcoming that the mass of masonry has grown up in the course of ages, old foundations being enlarged and covered in turn by new buildings. One of the most interesting discoveries made during the explorations is connected with the great hieroglyphic stairway which leads to the summit of one of the largest foundation mounds. The steps of this stairway had become disjointed and displaced, so that it is not easy to determine the exact plan of its construction; and it was probably in order to gain further information on this point that an excavation was commenced near the foot of the steps, which revealed the fact that the hieroglyphic stairway had been superimposed on an earlier stairway, which also had a clear cut inscription on the face of each step. A description of these stairways has been deferred until further exploration leads to a better understanding of their structure; and it is to be hoped that the greatest care has been taken in numbering and recording the position of the stones, so that the continuity of the glyphs in the inscriptions may be retained, as the result of a comparison of the initial dates of the two inscriptions (one of which is in the rarer form of picture writing) will probably prove to be of the greatest value.

FIG. 1.—Foot of the hieroglyphic stairway.

No regular burying-place has been found at Copan, but a number of isolated tombs have been explored, in which human bones were discovered in more or less disintegrated condition. The human incisor teeth were found, in many instances, to be ornamented by the inlaying of a little circular bit of jadeite, fitted into a hole drilled into the front of the tooth. These jadeite ornaments are slightly rounded outward, and highly polished. Many interesting pieces of pottery were secured during the excavations, some decorated with painted designs, others (such as the terra-cotta vase in the form of the head of a carnivorous animal, figured on p. 48 of the Report) remarkable for the artistic skill shown in the modelling. The most interesting object of all, however, was not a piece of pottery, but the actual skull of a peccary covered with beautifully incised figures and hieroglyphs. I have had the good fortune to be able to examine this skull in the Peabody Museum, and can only express an earnest hope that photographs of it, and drawings of the incised ornament, may be included in the further publications which are promised us.

During the second year's work a sad event occurred in the death of Mr. J. G. Owens, the leader of the expedition, who contracted a malignant fever during a journey to the coast, and died soon after his return to the ruins, where he lies buried in the great Plaza surrounded by those strangely carved monoliths in which he had learned to take so keen an interest.

The Exploration Committee of the Peabody Institute has not confined itself to organising expeditions in Honduras only; it has for some years worked with equal success in furthering the examination of ancient ruins in the peninsula of Yucatan. There, under the direction of Mr. Edward H. Thompson, for some time the United States Consul in Merida, a thorough examination has been made of the ruins of Labná; but, unfortunately, the report on that portion of the work has not yet been made public, and the second article in the *Memoirs* of the Museum deals only with the exploration of the Cave of Loltun,[1] which Mr. Thompson undertook in 1888 before setting to work at Labná—from which it is twelve miles distant—and continued in 1890–91.

One peculiarity of Yucatan is that it is a country without any rivers. The copious rainfall soaks through the porous limestone rock, and it is to the pools in the deep caves or "cenotes" that the Indian of to-day looks for his supply of water, as his forefathers did before him. Under such conditions the caves were sure to yield to the explorer many signs of human visitation, but it was of the greatest importance to ascertain whether the evidences of human handiwork should be attributed only to the race inhabiting the land at the time of the Spanish conquest, or

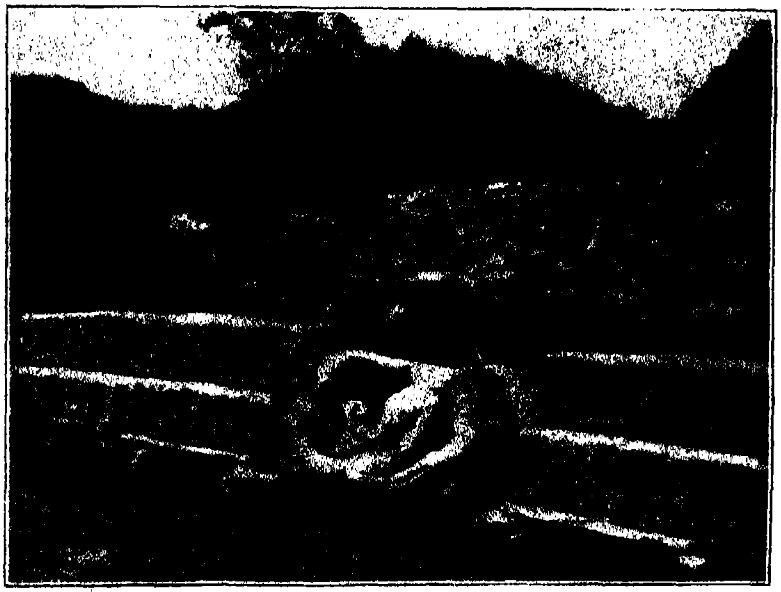

FIG. 2.—Two steps from the hieroglyphic stairway.

---

[1] *Memoirs of the Peabody Museum*, &c., vol. i. No. 2: "Cave of Loltun, Yucatan." "Report of Explorations by the Museum, 1888–89 and 1890–91," by Edward H. Thompson.

whether they could be ascribed to some earlier and more primitive race.

The interest attaching to the result of Mr. Thompson's labours has been somewhat discounted by the publication in 1896 of the admirable treatise on the caves of Yucatan by Mr. Henry Mercer, but to Mr. Thompson must remain the credit of having been first in the field.

Mr. Thompson's report is accompanied by some capital photographs of the rock carvings, taken by Mr. H. N. Sweet and Mr. M. H. Saville, showing them all to be rude and primitive in character, with the single exception of a life-sized human figure with the mutilated remains of a date expressed in the Maya notation above its head, which is just such a figure as one might find on the walls of the ruined temples above ground.

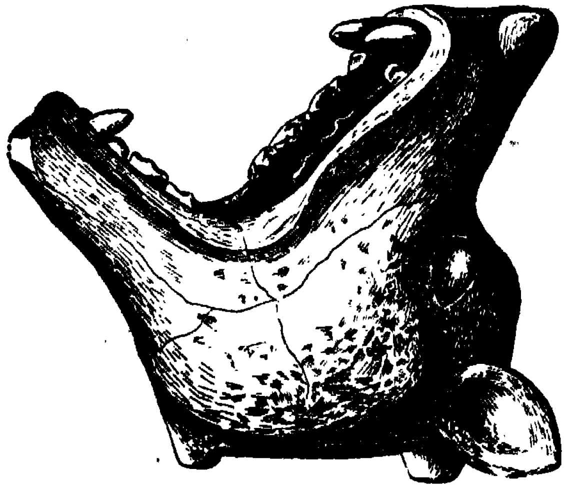

Fig. 3.—Terra-cotta vase (½ size.)

Mr. Thompson's main conclusion is that from the earliest period of the cave's use as a human habitation the people seem to have been of the same manners, religious customs, and household habits as those who built the great structures above ground now in ruins. Mr. Mercer, after pointing out that the caves were not properly dwellings but rather temporary halting-places, has given it as his opinion, (1) that no earlier inhabitant preceded the builders of the ruined cities of Yucatan; (2) that the people revealed in the caves had reached the country in geologically recent times; (3) that these people, substantially the ancestors of the present Maya Indians, had not developed their culture in Yucatan, but had brought it with them from somewhere else.

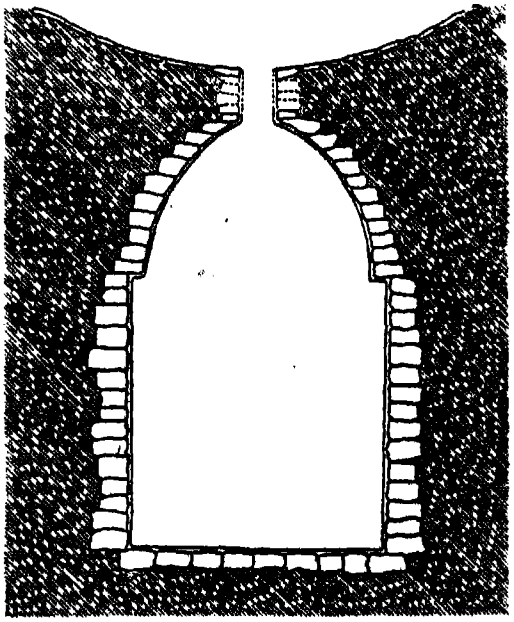

Fig. 4.—Section of a chaltune.

In a country where water is so scarce, it is only reasonable to suppose that the inhabitants would have devised some means of storing the precious fluid; and in the existence of numerous "chaltunes" we have almost certain evidence of the means of storage most commonly employed. These chaltunes are "single chambers of a vault-like appearance, built from ten to fifteen feet beneath the surface of the ground, and communicating with the outer world by means of a narrow well-like opening placed near the apex of the vaulted roof." They are somewhat irregular in shape, but the prevailing form is shown in the following section.

Mr. Thompson paid particular attention to the chaltunes amongst the ruins of Labná,[1] a neighbourhood where—if the opinion that they were used for the storage of water be correct—it is likely that they would be found in considerable numbers, as the nearest permanent water supply is found at the Cave of Loltun, twelve miles distant. Mr. Thompson is of opinion that many of the rougher class of chaltunes were formed in the cavities or pockets from which the white earth, called by the natives "zahcab," had been taken. "This earth is of a peculiar character, and served the ancient builders, as it does those of the present day, as a building material to mix with lime in place of siliceous sand, which is practically unknown in Yucatan." The other chaltunes are well-built chambers, having their walls, roof, and floor of dressed stones, and finished with a coating of fine, hard stucco. In the ruins of Labná, each edifice and each terrace was found to be provided with one or more of these subterranean chambers, the largest of which, however, would not hold more than 10,000 gallons.

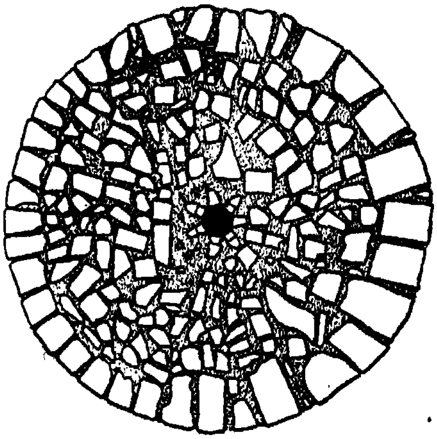

Fig. 5.—The mouth of a chaltune.

Many of the chaltunes had become hopelessly ruined, and many were filled up with earth and rubbish; but some of them had been purposely sealed up by the ancient inhabitants, and these presented a new and interesting field for investigation. Human bones and various objects of human workmanship were found among the deposits at the bottom of the chambers; and Mr. Thompson is led to the conclusion that many of these singular structures, after having been first used as reservoirs, were finally used as depositories for human remains, probably secondary burials, in connection with some special rite, after which the entrance of the chaltune was closed and cemented.

Alfred P. Maudslay.

P.S.—While the foregoing was in the printer's hands, an article on Copan has been brought to my notice, published in the *Century Magazine* for January, in which Mr. Gordon states that he has finished his work on the hieroglyphic stairway. It proves to have been a single flight of steps, and not one stairway built over another. The illustration given on p. 569 shows the foot of the stairway as it was at first disclosed by Mr. Owens's excavation. The disjointed stones of the upper part of the stairway (some of which have already been cleared away) had slid down bodily from above and, until the excavation was made, had completely hidden the lower part of the stairway.

---

[1] *Memoirs of the Peabody Museum*, vol. 1. No. 3: "The Chaltunes of Labná, Yucatan." "Report of Explorations by the Museum 1888-89 and 1890-91," by Edward H. Thompson.

It is to be hoped that the next part of the *Memoirs of the Peabody Institute* will give the details of this interesting work, and a more accurate (if less ambitious) drawing than that of the "restored" stairway published in the *Century Magazine*. If it has been possible to preserve the continuity of the inscription on the steps, Mr. Gordon's labours will have added to our store one of the longest and most valuable inscriptions yet found in Central America.

Surely it is through an unintentional error that the drawing of the Jaguar stairway, on page 409 of the *Century*, is ascribed to Henry Sandham. A. P. M.

RECENT PAPERS ON GLACIATION.

AT the Toronto meeting of the British Association the numerous papers bearing on the glaciation of the North American continent were of exceptional interest to the British student of glacial geology, inasmuch as they brought prominently to mind the methods adopted by the Canadian and American glacialists, which differ in many respects from those to which we have become accustomed on this side of the Atlantic.

In no branch of earth-lore is the influence of his environment more strongly impressed upon the worker than in stratigraphical geology, and the effect of the simple topographical forms and of the enormous extent over which the glacial deposits are distributed in North America, has been to give a broader grasp and bolder tone to the general run of its glacial literature. This was admirably illustrated by the work brought forward at the meeting. In the British Islands, from the abundance of natural and artificial sections as well as from the complexity and narrow limits of the topography, the lithological composition of the drift deposits is usually made the pivot of the studies, while in America it is rather the arrangement of the drift in regard to the general physical features which is held to be of paramount import.

The following comments on the papers read at Toronto have been written from the standpoint of a British glacialist anxious to find wherein he might profit by the adoption at home of the Transatlantic methods.

To realise the extent of the field in North America it must be remembered that the total area of the Dominion of Canada, about 3,616,000 square miles or not much less than the whole of Europe, can show, in one form or another, traces of the Great Ice Age in every part, and that the same glaciated area further extends over a region about one-fifth as large to the southward of the Canadian border. It is not surprising, then, that the study of glacial phenomena should have attracted so many able workers in Canada and the United States.

The exploratory work of Russell, Wright and others upon the existing glaciers of Alaska, and of Chamberlin, Peary, Barton and others upon the edge of the ice-sheet in Greenland has been more readily assimilated by American than by British glacialists, and its influence is perceptible throughout their researches. It is true that the Danish explorers had already made known to us the leading facts relating to the latter region, but their studies were not perhaps made so directly from the standpoint of the glacial geologist as those of the above-mentioned observers, nor were their results so accessible to the English-speaking geologists. But since Russell, by his investigation of the Malaspina Glacier, with its forested moraine-covered margin sheltering a varied fauna and flora, has shown how widely different are the conditions of Piedmont ice and Alpine glaciers, and since Chamberlin, in describing the mode of occurrence of the detrital matter in the basal layers of Greenland ice-tongues, has thrown so much new light on the whole question of drift-deposition, the British glacialist would do well to recognise, with his colleagues across the Atlantic, that the glaciers of the Alps do not afford the best introduction to the study of glacial geology. It is clear that the Alpine conditions are, in many respects, very different from those under which the ice-sheets of the Glacial period did their work.

As regards the cause of the Great Ice Age, we heard at the Toronto meeting two interesting communications. That of Prof. T. C. Chamberlin, outlined in a former number of NATURE (September 16), was avowedly altogether speculative, and belonged to the domain of earth-physics rather than to geology in the ordinary sense. The other was that in which Dr. J. W. Spencer ably advocated his well-known views on the continental elevation of the Glacial epoch.

Dr. Spencer described a large number of drowned valleys, often extending from the mouths of the great modern rivers across the submarine plateaus at various depths, reaching to even 12,000 feet or more, and recognisable as far northward as Labrador. He stated that upon tracing northward the deposits occupying the great valleys, he found that glacial accumulations occur in New Jersey between the Lafayette formation, which is the latest horizon dissected by the great valleys, provisionally regarded as of late Pliocene age, and the Columbia formation, which is mid-Pleistocene. From all these considerations he concluded that the eastern portion of North America stood more than two miles above the sea during the earlier Pleistocene epoch.

On other evidence he judged that the Mexican plateau was mostly depressed to near sea level during the times of the high elevation of the eastern portion of the continent; and that, with the subsidence of the eastern region, the western side of the continent was elevated from 6000 to 10,000 feet or more. The separation of the Atlantic and Pacific Oceans he regards as only of recent date. These changes of levels and the dependent variations of currents, &c., seem, in his opinion, to be sufficient cause for the Glacial period.

As Dr. Spencer pointed out, his views are practically those which have been advocated by Lyell and many others. But while a pre-glacial elevation of the North American continent is generally acknowledged by geologists, the extent of this elevation is not usually admitted to have been even approximately as large as Dr. Spencer would claim, and the difficulties in accounting for the widespread glaciation of the Northern Hemisphere by the effects of elevation alone are so great that the defenders of this hypothesis are at present few.

There is a somewhat remarkable blank in the evidence to hand in North America as to the conditions immediately antecedent to the Glacial Period, nothing equivalent to the Forest Bed Series and associated pre-glacial deposits, of which we possess such excellent sections on our Norfolk coast, having yet been discovered. For this reason the paper of Mr. R. Chalmers, of the Geological Survey of Canada, on the pre-glacial decay of rocks in Eastern Canada, was of especial interest. Mr. Chalmers showed that in the region he described, beds of decomposed rock, of variable thickness and more or less modified, occur wherever the surface of the rocks has not been abraded by Pleistocene ice, though boulder clay may often be found overlying them.

He gave the following general section of these beds in descending order:—(1) Transported and stratified water-worn gravel with beds of fine sand and clay. (2) Coarse stratified gravels, usually yellow and oxidised, the materials wholly local. (3) Sedentary rotted rock, passing into solid rock beneath.

There seems at present to be no evidence as to the precise age of these beds in Eastern Canada; but Mr. Chalmers pointed out that somewhat similar deposits occurring at the western base of the Green Mountains in Vermont, have yielded vegetable remains by which Lequereux, many years ago, referred them to the Miocene. He concludes that the general aspect of the dry land in Eastern Canada previous to the Glacial period must have been nearly similar to that of the region south of the glaciated zone in North America.

The occurrence of similar local rubble in sheltered situations beneath the drift has often been noted in the British Islands, and the ease with which such loose-lying material would become incorporated into the basal layers of an advancing ice-sheet has been frequently discussed. On both sides of the Atlantic it seems more probable that the greater bulk of the glacial deposits was derived from this source, rather than from the direct erosive action of the ice upon the solid rocks.

With regard to the initial stages of the glaciation, while the European glacialist looks to the highest ground in the northern part of his continent and its islands—to the mountains of Scandinavia, of Scotland, England, Wales and Ireland, and of Switzerland—as the great gathering grounds, it is generally recognised that in North America, with the exception of the Cordilleran mass in the extreme west, the glaciation commenced and spread from the comparatively low ground in the north of the continent and moved southward against the slope of the land, the mountains near its south-eastern margin being obstacles in its course rather than aids to its accumulation. It is, indeed, probable that in Eastern Europe too much stress has been laid on the importance of the hill-ranges as glacial centres, since there is much evidence to indicate that, at any rate during the maximum glaciation, the movement, and probably therefore the growth, of the great sheets was more or less independent of the orographic features. In this connection the explorations of Mr. J. B. Tyrrell, of the Canadian Survey, in that birthplace of ice-sheets the desolate region to the westward of Hudson Bay, are of the highest importance. In his paper on the glaciation of North-western Canada, Mr. Tyrrell stated that no evidence was discovered of any great elevation of this central area in Glacial, or immediately Pre-glacial times, and it would seem not improbable that the land then stood at about the same height above the sea as at present; and that the moisture giving rise to the immense precipitation of snow would probably be derived from the adjacent waters of Hudson Bay and the Arctic Ocean.

In the region immediately west of Hudson Bay, the earliest glaciation of which he could recognise any traces flowed outwards from a gathering-ground which lay north or north-west of Doobaunt Lake. Subsequently this gathering-ground moved south-eastward, until it centred over the country between Doobaunt and Yath-kyed Lakes. From one or other of these centres the ice seems to him to have flowed westward and south-westward to within a short distance of the base of the Rocky Mountains; southward, for more than 1600 miles to the States of Iowa and Illinois; eastward, into the basin of Hudson Bay; and northward, into the Arctic Ocean.

He applies the name Keewatin Glacier to this central continental ice-sheet, which in general character appears to have been somewhat similar to the great glacier of north-western Europe, with a centre lying near the sea-coast, a steep and short slope seaward, and a very much longer and more gentle slope towards the interior of the continent. But, remarked Mr. Tyrrell, there was this difference between the two, that the centre of the latter was over a high rocky country; while the centre of the former was over what is now, and was probably also then, a low-lying plain, on which the snow accumulated to such depths as to cause it to flow over country very considerably higher.

This great glacier, in the different stages of its retirement down gradually descending slopes, caused many temporary extra-Glacial lakes to be formed, which were drained one after another as it retired to still lower country. Before it had withdrawn from the Winnipeg basin, Mr. Tyrrell thinks that it was joined by an advancing glacier from the east, and in front of the two, Lake Agassiz, one of the largest of the extra-Glacial lakes, was formed. During the final stages, its general gathering-ground is believed to have moved still nearer to the coast of Hudson Bay, and to have broken into several separate centres; and Mr. Tyrrell notes that after its retirement the land in the vicinity of Hudson Bay stood from 500 to 600 feet below its present level, and gradually rose to its present height.

The shifting of the centres of glaciation at different stages of the Great Ice Age, to which Mr. Tyrrell referred, seems to be a well-recognised characteristic in North America, though it is diversely explained. Dr. G. M. Dawson, in the admirable summary of Canadian Geology in the new Handbook for Canada prepared for the Toronto meeting, notes that the western part of the Great Plains was invaded at an early stage by large glaciers issuing from the Cordilleran ice-sheet through the main valleys of the Rocky Mountains, while at a later period, when this ice had shrunk back, a newer series of glacial deposits was spread out in the same area, largely composed of Laurentian and Huronian débris transported from the north-east.

Dr. Dawson, while acknowledging that the evidence is not satisfactory, is still inclined to think that these latter deposits may be in part of marine origin, and that they indicate great relative and absolute changes of level in this region in Glacial times.

In eastern Canada also "it has been found by Mr. Chalmers that when the Laurentide Glacier invaded the lowlands to the west of Quebec, the Appalachian glacier had either greatly decreased or had vanished" (Handbook, p. 30).

In England the drift deposits of the eastern and midland counties show many similar indications of successive glaciation from different centres, and until recently the tendency has been, as in America, to ascribe the facts to the intervention of warm inter-glacial periods. But since it is now generally acknowledged that, given a sufficiently low temperature, the prime factor in the accumulation of the ice-sheets has been the excessive snowfall rather than the extreme cold, may not the whole of the phenomena have been due to the gradual shifting of the areas of greatest precipitation, brought about, as a secondary effect, by the growth of the ice-sheets themselves?

It will be observed that Mr. Tyrrell, in common with all American glacialists, has recognised an up-hill movement of the ice sheet. The possibility of such movement has frequently been questioned on our side of the Atlantic, in spite of the occurrence of transported boulders in various parts of the British Islands at levels considerably higher than their source. But the extent of the uplifts in such instances is slight as compared with that described by Prof. C. H. Hitchcock in his paper on the Southern Lobe of the Laurentian Ice-sheet.

Prof. Hitchcock pointed out that one great lobe of the Laurentide Glacier went southward through the Champlain and Hudson valleys, moving from a plain near sea level, over the highest mountains in New England and New York, 6000 and 4000 feet in altitude, as shown by the transport of the boulders and by the direction of the glacial striæ. As indicative of the distinctiveness of this lobe he described how the striæ diverge from the central line "much like the barbs of a feather from the central shaft," and how the terminal moraines are looped round the area rudely at right angles to the direction of the ice movement. The initial gathering ground for this portion of the ice-sheet seems to have lain to the eastward of Hudson Bay; hence it is sometimes termed the Labradorian Glacier.

The lobate character of the southern termination of the ice and the tendency of these lobes to spread outwards from a centre is strongly insisted upon by all the American glacialists who have studied the peripheral portions of the glaciated area, and the delimitation of these lobes and the discussion of their chronological relations has been made the subject of much recent research. The matter is worthy of more attention than it has yet received with us, for as was shown by Mr. H. B. Woodward in a paper, read at Toronto, on the Chalky Boulder-clay of our West-midland counties, some at least of the characteristic phenomena can be recognised in this country also. The fact that in America these distinct lobes did not reach their maximum development at the same time, and that the overlapping of one great tongue upon the area previously occupied by another is frequently indicated, has given rise to much difference of opinion as to the length of the time-interval separating these different stages of growth and retreat. Prof. T. C. Chamberlin, who gave a lucid demonstration of his views[1] at Toronto, is of opinion that the glacial phenomena of the northern United States indicate two or more successive and distinct periods of glaciation separated by mild interglacial intervals, while other observers are inclined to agree with Dr. G. F. Wright, who though acknowledging wide oscillations of the ice-margin, regards the growth and wane of a single sheet as sufficient to account for all the facts.

In America, therefore, as in Europe, in spite of the prolonged discussion, not only is the number of the supposed warm inter-glacial periods still unsettled, but the evidence for even one such interval is challenged. The whole question is largely a legacy from the brilliant theorising of the late Dr. J. Croll, and with the breakdown of his captivating generalisations it has become necessary to reconsider the whole evidence which has been adduced, in support of them, on both sides of the Atlantic, before a safe conclusion can be reached. It is suggestive that while the explorers of the peripheral areas of the old ice-sheets are usually steadfast in their belief in such periods, those whose investigations lie more centrally to the regions of accumulation, both in Europe and in America, are more frequently in favour of the unity of the great glaciation. Yet even this localisation of opinion is capable of two opposite applications.

One of the strongest threads in the evidence for an inter-glacial period in North America is furnished by the sections in the vicinity of Toronto. Since Dr. G. J. Hinde described these deposits in 1877, fresh excavations in the Don Valley have revealed new facts of importance. Prof. A. P. Coleman, in his paper on the subject at the British Association meeting, stated that in the Don Valley a lowest till is seen, upon which rest 18 feet of sand and clay containing many unios and other shells, as well as leaves and pieces of wood. Some of the unios do not now live in Canadian waters, but are found in the Mississippi; and several species of trees now belonging to the States to the south occur with them, indicating a climate decidedly warmer than the present. Above this come stratified clay and sand, with a caribou horn and remains of insects and plants belonging to a colder climate than the present. This set of clays and sands is best shown in the cliff-section at Scarborough Heights a few miles to the east, where the series rises 148 feet above Lake Ontario, and contains many species of extinct beetles, as well as shell-fish, mosses, and wood of hardy trees. A complicated middle till overlies these beds which were deeply eroded before the advance of the ice. Another less important fossil-bearing bed occurs above the middle till at elevations up to 240 feet above the lake, and is followed by a third till. Prof. Coleman notes that great changes have occurred in the level of the water, the lake being much lower than at present before the first glacial advance and after the first interglacial time, and that during the deposition of the middle till, and also while the last sheet of till was being deposited, the water stood from 250 to 300 feet above the present level of the lake, which is 247 feet above the sea. In his opinion the length of time required for the first interglacial period is probably to be estimated at thousands of years; and during this time he thinks the ice-sheet of the Laurentide Glacier must have completely disappeared.

---

[1] These are ably stated by Prof. Chamberlin in the chapter on the Glacial phenomena of North America in the third edition of Prof. Jas. Geikie's "Great Ice Age."

As a result of this paper a British Association Committee was appointed to investigate these deposits further by means of excavations. The palæontological evidence is held to imply that, as above stated, the climate when the Don Valley deposits were laid down was such as would be incompatible with the presence of ice anywhere in the Laurentide area, and that this warm period was followed by a later glaciation, of which the clearest evidence is contained in the section at Scarborough Heights. The identification of the warm-climate horizon in this cliff-section is especially desirable, and is one of the results which may be hoped from the Committee's investigations.

In describing the drift phenomena of the Pacific coast around Puget Sound, which in most respects compare very closely with those of our own islands, Mr. Bayley Willis put forward the hypothesis that the channels of the Sound, which have usually been considered submerged valleys, are the hollows remaining after repeated glacial invasion of a wide and diversified depression, during which the earlier divides were built upon, and transformed into plateau like eminences of glacial drift, whereas the occupation of the valleys by glacial ice, particularly in the stagnant stages of retreat, prevented their being permanently filled; so that with the final retreat of the ice the moulds of glaciers remained as the channels of the Sound.

This view accentuates the undoubted fact that the accumulation of glacial débris has been greater around the margins of the old ice lobes than in the more central areas, and it may be applied to some extent to our own islands, where the persistence since pre-glacial times of the shallow basins of the North Sea and the Irish Sea appears to indicate that a larger proportion of the material transported by the ice-sheets which once filled them has been deposited around their margins than within their beds.

The old lake-beaches, incidentally referred to by Prof. Coleman and Mr. Tyrrell, occupy a large place in the studies of the American glacialists, while in the British islands, in spite of the rough pioneer work of the late Prof. Carvell Lewis, the subject has scarcely been touched. The scope for these researches in our country is, of course, limited; but the classical example of the parallel roads of Glen Roy is sufficient to prove that the phenomena are not unrepresented. In America two distinct types of old lakes have been recognised—those like Lake Agassiz and Lake Warren, which were formed in front of the retreating ice-margin, and those like Lake Nipissing and Lake Iroquois, which owed their position to differential earth movements.

The literature in regard to both types is already very-extensive, and is not altogether satisfactory. Especially in the case of the glacially-dammed waters, their reputed vast extent, their impersistence of level and brief duration, the later modification of their sites by earth movements, and above all the obscurity of their traces over wide tracts of uncleared forest, makes it certain that while the broad fact of their former existence may be undoubted, the delimitation and correlation of their boundaries must be regarded in most cases as more or less provisional. With gravelly deposits of all kinds spread over such an enormous extent of territory it must necessarily be difficult to pick out an individual shore-line unless this can be traced almost continuously, which is rarely possible. In certain regions, however, the study has been carried on under more favourable conditions, with most interesting results. Thus Prof. H. Leroy Fairchild, in describing the glacial phenomena of Western New York,[1] showed how the long upland valleys of that part of the State contain the terraces of lakes which have overflowed southward across the watershed, leaving well-marked channels of glacial drainage, and how as lower passes were opened by the retreating ice the waters of these lakes sank to corresponding levels. The highest of the continuous shore-lines of this region is recognised as being that of the glacial Lake Warren, which is believed to have stretched from the western end of the basin of Lake Ontario over the whole or the greater part of the Great Lakes.[2]

Below this are found several less continuous terraces, probably marking different stages of the depletion of the lake, until at about 500 feet lower the Iroquois shore-line is reached, which appears to have been the immediate forerunner of the Lake Ontario of the present day. This beach is admirably developed in the vicinity of Toronto, and the main facts regarding it were demonstrated by Mr. Gilbert and Dr. Spencer during the meeting. Dr. Spencer considers that it is an old sea-beach; but in this he is at variance with most of the American glacialists, who hold that it, like the higher beaches, is of fresh-water origin.

These old beach-lines are of especial importance in that they reveal considerable differential uplift during late-glacial and post-glacial times. On this point all the students of the subject are agreed, and it is, of course, regarded therefore as a factor of prime importance in the later history of the lake basins. It was insisted upon by Mr. F. B. Taylor in an interesting communication on the relation of the Champlain submergence to the Great Lakes and to Niagara Falls. Working on the same lines as Mr. Gilbert had done, Mr. Taylor showed that an old shore-line, named the Nipissing Beach, surrounds a large portion of the Upper Great Lakes, and leads to a low col at the east end of Lake Nipissing. The formation of this beach he supposes to have been contemporaneous with the Champlain submergence by which the St. Lawrence Valley and the Champlain depression became arms of the sea, so that during this period the Upper Great Lakes had their outlet by way of the Nipissing Pass and the Ottawa River into the St. Lawrence, leaving only the discharge of Lake Erie, or one-ninth of the total volume, to occupy the Niagara River. Mr. Taylor stated that the Nipissing beach is tilted so that it falls regularly towards S. 27 W. at the rate of nearly 7 inches to the mile, being 110 to 115 feet above the present surface of the north-eastern part of Lake Superior, while not far east of Duluth it has sunk to the water level, and if its plane were projected it would pass 100 feet below the lake-level at Chicago. He gave reasons for considering that the tilting was caused by the same uplift which raised the Champlain Valley, and that one effect of this movement was to close the Nipissing outlet and to open that at Port Huron, by which the entire discharge of the lakes was sent into the Niagara. The result of these changes is to be found, according to Mr. Taylor, in the cañon below the Falls, the narrow and shallow gorge of the Whirlpool Rapids indicating the work of the comparatively feeble stream from Lake Erie, while the Upper Great Gorge has been excavated since the closing of the Nipissing outlet, which, accepting the known rate of recession of the Horse-shoe Fall as the principal datum, may have taken place from 5000 to 10,000 years ago.

These researches may well serve to illustrate the complexity of the problem whenever an attempt is made to transmute the term of geological processes into an equivalent in years. Simple multiplication and division without a steady-going chronometer can never suffice, nor is the time-unit that serves for a man's life ever likely to help us much in measuring the duration of cosmic processes.

As regards the differential movement, Spencer and Gilbert are of opinion that it is still in progress, and will eventually submerge Chicago and dry up Niagara. In a recent paper[3] Gilbert has even ventured to predict in years when this may be expected.

G. W. L.

---

[1] This paper is printed in full in the *Geological Magazine*, and is therefore easily accessible to British geologists.

[2] An admirable summary of the work of Spencer, Gilbert, and others in elucidating the history of this great body of water will be found in a paper by Mr. Warren Upham on "Glacial Lakes in Canada," *Bull. Geol. Soc. of Am.*, vol. ii. (1891) pp. 243–276.

MIERSITE, A CUBIC MODIFICATION OF NATIVE SILVER IODIDE.

SILVER IODIDE is remarkable in being one of the few substances which undergo a contraction in volume as the temperature increases. This contraction is uniform until about 146° C. is reached, when there is a further sudden contraction of considerable amount, after which the substance expands. The sudden contraction at 146° is accompanied by a change in all the physical properties of the substance, the pale yellow, hexagonal modification which exists at ordinary temperatures, being then changed into a bright yellow, cubic modification. On cooling the reverse phenomena are observed.

From this behaviour it would be expected that only the pale yellow, hexagonal modification would be found as a natural mineral, and as a matter of fact the only pure silver iodide so far known is the hexagonal species iodyrite. The existence of a cubic modification has, however, long been suspected from the occurrence of iodine in the cubic mineral iodobromite ($2AgCl.2AgBr.AgI$). This probably represents the artificial cubic modification which is stable above 146°, in which case the natural crystals of iodobromite should be pseudo-cubic; in fact, pseudomorphs of the hexagonal modification with the external form of the cubic modification. This would be strictly analogous to the pseudo-cubic leucite and boracite, which become isotropic when heated to a definite temperature.

The new mineral, miersite, is, however, quite distinct from these, and proves that silver iodide is trimorphous. The principal characters of the three modifications are :—

Iodyrite	Miersite	Iodobromite
Hexagonal	Cubic	Cubic
Hemimorphic	Tetrahedral	Holohedral
Twin plane, a pyramid face	A tetrahedron face	Not twinned
Cleavage, perfect basal	Perfect dodecahedral	Indistinct octahedral
Optically uniaxial	Isotropic	Optically anomalous?
Sectile	Brittle	Sectile

Between these there is a remarkable crystallographic relation: when a regular octahedron is considered as a rhombohedral crystal, the angle 70° 32′ corresponds to the angle 70° 36′ between the basal plane and a pyramid of iodyrite; the tetrahedrism, twinning, and sometimes the peculiar development of the miersite crystals make this relation still more striking.

Iodyrite, in all its crystallographic characters, is practically identical with wurtzite (ZnS), greenockite (CdS), and zincite (ZnO); these are all hexagonal and hemimorphic, possess a basal cleavage, and are optically positive, while the axial ratios vary only very slightly ($a : c = 1 : 0{\cdot}8109 - 1 : 0{\cdot}8196$). Many other substances may perhaps be included in this series, *e.g.* ice, magnesium, cadmium iodide, tridymite (SiO_2), &c. In the same way the dimorphous cubic modifications miersite, blende (ZnS), and marshite (CuI) form another parallel series, since they are all exactly alike in crystallographic characters.

It will now be seen that the same relation exists between iodyrite and miersite as exists between wurtzite and blende. This forms, as far as crystallographic characters are concerned, a perfect example of an isodimorphous group, but apparently the only relation existing between zinc sulphide and silver iodide is that their simplest conceivable chemical molecules contain two atoms.

From these somewhat remarkable relations one is inclined to ask: why should there not be a third modification of zinc sulphide to correspond with iodobromite? or why should not all these substances (*e.g.* ice, &c.) be dimorphous or trimorphous to fill up the gaps in these parallel series? Further, if nantokite and marshite are to be represented by the formulæ Cu_2Cl_2 and Cu_2I_2 respectively, then miersite should be Ag_2I_2: these double molecules, however, only depend on the vapour density of cuprous chloride, but the gaseous molecule cannot be the same as the crystal molecule, especially when there are, as in silver iodide, possibly three types of the latter.

A detailed description of miersite will be published in the *Mineralogical Magazine*. It may now be mentioned that the two specimens preserved in the British Museum collection are from the Broken Hill silver mines in New South Wales; the associated minerals on one specimen are quartz, copper glance, and garnet, and on the other, malachite, wad and anglesite. The small crystals of miersite, which do not exceed 2 mm. in diameter, are scattered over the surface of the matrix; they are of a pale or bright yellow colour, with an adamantine lustre. The only forms present are the cube and one or both of the tetrahedra, the latter usually differing in size but not in surface characters. In many respects the mineral is strikingly similar to the yellow blende which occurs in the white dolomite of the Binnenthal in Switzerland. The bright yellow streak is sometimes deeper in colour than the crystals themselves; this is strikingly shown by perfectly colourless and transparent crystals of marshite, which also give a bright yellow streak. Exposure to bright sunlight for several days does not affect the colour of the crystals. The silver is in part replaced by copper, and as this increases in amount, there is a gradual passage from miersite to marshite: "cuproiodargyrite" ($AgI.CuI$) from Chili is possibly an intermediate member of this group.

The new mineral has been named in honour of Mr. H. A. Miers, F.R.S., Professor of Mineralogy at Oxford, who first correctly determined the crystalline form of marshite, a mineral so closely resembling miersite in appearance that the two species are only to be distinguished by chemical tests.

L. J. SPENCER.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

THE Maryland Senate has passed a Bill granting 50,000 dollars a year for two years to the Johns Hopkins University.

DR. CHARLES CHREE, Superintendent of Kew Observatory, has received the honorary degree of LL.D. from the University of Aberdeen.

MR. C. B. ROUSS, who gave 25,000 dollars for a physical laboratory building in the University of Virginia, has given an additional 10,000 dollars for the same object.

MR. CHESTER W. KINGSLEY, of Cambridge, Mass., has given several large gifts to various benevolent purposes, including the sum of 25,000 dollars each to the Newton Theological Seminary, Andover Academy, and Colby University; the two first named being situated in Massachusetts, and the last in Maine.

A COURSE of eight Yates lectures in Archæology will be commenced at University College, London, on May 4, by Mr. J. Romilly Allen. The subjects of the first two lectures are the origins of primitive art and the evolution of decorative art, and the general object of the course is to trace the developments of Celtic art.

THE first school of forestry in America has just been created by the legislature of the State of New York, to be connected with Cornell University, and the sum of 10,000 dollars has been granted to cover the expenses of the first year. The school is authorised to purchase forest lands to the extent of 30,000 acres in the Adirondack region.

THE University of Paris has (says the *Times*) arranged for a loan of 1,700,000 francs from the Crédit Foncier, repayable in 50 annual instalments, for the erection of new buildings in Paris and at Fontainebleau. The Faculty of Science is also about to order the construction at a cost of 25,000 francs of an equatorial, which, after figuring in the Exhibition of 1900, will be placed in the tower of the new Sorbonne.

AT the graduation ceremony of the Glasgow University on April 12, the honorary degree of Doctor of Laws (LL.D.) was conferred upon Mr. Alexander Duncan, Secretary and Librarian to the Faculty of Physicians and Surgeons, Glasgow; Mr. Douglas Dunlop, Secretary-General to the Department of Public Instruction, Cairo, Egypt; Mr. John Inglis, formerly president of the Institution of Engineers and Shipbuilders in Scotland, president-elect of the Institution of Marine Engineers, London; Dr. Elie van Rijckevorsel, of the Batavian Society of Experimental Philosophy, Rotterdam; and Prof. J. M. Thomson, F.R.S., professor of Chemistry in King's College, London.

THE excursions of the London Geological Field Class will begin on Saturday, April 23, with a visit to Dorking, Box Hill, and Betchworth; and between that date and the middle of July the country from Aylesbury to Cuckfield will be systematically examined by the class so as to draw a section over the trough of the Thames basin, and see the deposits to the north and south of London, which underlie the rocks associated with the chalk. The class has been organised and carried on by Prof. H. G. Seeley, F.R.S., for the past twelve years, without difficulty of any kind, and without assistance. It was established as a class to show that systematic instruction in geology could be given in the open country, and the example it affords must tend to bring about more practical teaching in the matter of field-work. When the class began there was very little of such teaching anywhere, but the value of individual observation is now accepted as a canon of scientific education, and the success of Prof. Seeley's work should encourage educationists in their endeavour to get the fact-knowledge entirely substituted for the word-knowledge of books.

SOCIETIES AND ACADEMIES

DUBLIN.

Royal Dublin Society, March 16.—Prof. G. F. Fitzgerald, F.R.S., in the chair.—Prof. J. Joly, F.R.S., and Dr. H. H. Dixon read a paper on the distribution of coccoliths and on some microscopic organisms found in Dublin and Killiney Bays. Coccoliths have been found by the authors on the Irish coast at Sligo, Slyne Head, Dingle, Waterville, and along the coast of south Co. Dublin, and on the south coast of England at Weymouth. Samples of water from Loch Inver and Portstuart did not afford any examples. Coccoliths were also found in the mud obtained in the Severn and Liffey beds. In the paper are also described a new marine Difflugia and organisms from Killiney Bay resembling Ehrenberg's Pyxidicula and Xanthidia from the chalk.—A paper by Prof. W. Noel Hartley, F.R.S., and Mr. Hugh Ramage was then read by the former, the subject being a determination of the wave-lengths of the principal lines in the spectrum of gallium, showing their identity with two lines in the solar spectrum. The authors have found gallium to be a very widely distributed element in the earth, and to be present also in meteoric bodies. It became natural to inquire if it is present in the sun. The wave-lengths of the two principal lines have not previously been determined by a grating spectrograph, and the authors availed themselves of the kind offer of Dr. Adeney to allow them to photograph spectra of gallium with the 21½ feet radius grating spectrograph in the Physical Laboratory of the Royal University of Ireland. The two principal lines were photographed as bright and reversed lines in arc spectra, and as bright lines in the spark spectrum of a solution of gallium chloride. In these and in the oxyhydrogen spectrum of gallium compounds the less refrangible line is always stronger than the other. The wave-lengths of the two lines, determined by interpolation from adjacent iron lines, are found to be 4172·215 and 4033·125. In Rowland's map of the solar spectrum there are two lines probably identical with these, namely:—

4172·211. Source: Aluminium. Intensity: 1,
and 4033·112. Not identified. ,, 00.

It is pointed out that gallium is present in every bauxite and shale examined by the authors, and also in metallic aluminium, and no doubt the line 4172·211 in the spectrum of aluminium is really a gallium line. From the very close agreement of the wave-lengths, from the relative intensities of the lines as shown above, and from the evidence of the wide distribution of the element, it seems certain that the two gallium lines are identical with the two lines above mentioned in the solar spectrum, and there are no other lines so close to these. The evidence is discussed at length in the paper, as also is the effect of the presence of elements upon the spectra of other elements.—Prof. J. P. O'Reilly read a paper on the occurrence of anatase and brookite in the quartzites of Shankill, Co. Dublin. He explained that the minerals were found in a mass of yellow earth, met with by the quarrymen in 1888, and had only lately been examined. The peculiarity of the anatase was its approximation in composition to the clay or mineral analysed by Eakins as mentioned by Dana in his "System of Mineralogy," edition of 1892, p. 716, while presenting the crystalline form of anatase, thus allowing of the presumption that the clay analysed by Eakins and called by him "Xanthitane," was probably the product of decomposition of an anatase having much the same composition as the mineral found at Shankill.

EDINBURGH.

Royal Society, March 21.—Lord Kelvin, President, in the chair.—Lord Kelvin, in a paper on thermodynamics, deduced from motivity, fulfilled a promise made twenty-one years ago to the Society. After referring to the somewhat misleading phrase, *the mechanical equivalent of heat*, and pointing out the necessity of having a single word to express the availability of heat for transformation into useful work, he proceeded to show that the whole of thermodynamics was contained in the two equations

$$
\begin{aligned}
de &= \mathrm{J N}dt + \Sigma(\mathrm{P}dg + \mathrm{JM}dg) \\
dm &= \mathrm{J}\frac{t-\mathrm{T}}{t}\mathrm{N}dt + \Sigma\left(\mathrm{P} + \mathrm{J}\frac{t-\mathrm{T}}{t}\mathrm{M}dg\right)
\end{aligned}
$$

where e is the energy, m the motivity, t the temperature of any part of the system, T the lowest temperature in the system, g any coordinate, P the corresponding force, and N, M specific heats. The usual equations are at once deduced by treating de, dm as complete differentials.—Dr. Galt, of Glasgow University, communicated a paper on the microscopical appearances of the grains in the more commonly occurring starches. The paper was full of detail, and was illustrated by numerous original photographs and lantern slides. In a paper on methods of mapping rainfall, Mr. A. J. Herbertson described a simple graphical method for taking into account the varying lengths of periods of observation of rainfall at different parts of the globe. The mean rainfall values were inserted on the maps in different coloured inks, according to the length of period of observation. The general trend of the isohyets could be attained by comparing similarly coloured means, and the final positions of the lines fixed by the values at the stations with the most extended records. The variableness in the length of the month is allowed for by drawing isohyetal lines, whose actual values are the nominal values multiplied by the days in the corresponding month, and divided by one-twelfth of a year expressed in days. In a second paper, on the normal rainfall of India and the abnormalities in 1896, Mr. Herbertson showed maps on the mean annual and monthly rainfall of India, based on the means published in the rainfall data for 1895, and those in the annual summary for 1896.

Royal Physical Society, March 16.—Mr. B. N. Peach, President, in the chair.—Papers were read by Mr. W. S. Bruce, of the Jackson-Harmsworth expedition, and Mr. William Eagle Clark, on the mammals and birds of Franz Josef Land. Mr. Bruce, who spent fifteen months on Franz Josef Land in 1896-97, explained that the number of species, exclusive of mammals and birds, he then obtained exceeded that of any previous Arctic expedition, he having secured 236 against 216 to the credit of the United States expedition of 1881-83. He had at least doubled the number of species known to Franz Josef Land. He had found ancient reindeer horns, though there were no reindeer at present in the Land. Among the specimens he exhibited were the bones of whales and walruses found on raised beaches with an elevation of from 50 to 80 feet, plainly indicating their great age; while one specimen—the scapula of a walrus—was found at a height of 336 feet. The chief point of interest in Mr. Clark's part of the subject, which was restricted to birds, was the finding of several new species—Bonaparte's sandpiper, purple sandpiper, and the shore lark. The first mentioned of these, Mr. Clark said, was not only a new and remarkable addition to the ornis of Franz Josef Land, but it was the first authentic example of this American species that had been obtained in Europe elsewhere than in the British Isles. Another subject of interest in the paper was the description of a newly-found nesting-place of the ivory gull. This was at Cape Mary Harmsworth, on what was considered to be one of the largest pieces of bare ground in Franz Josef Land. Of the twenty-two species of birds which formed the avifauna of Franz Josef Land, only ten had been found breeding, though several more undoubtedly nested there, while several, again, were mere stragglers.

PARIS.

Academy of Sciences, April 4.—M. Wolf in the chair.—On a doctrinal point in the theory of quadratic forms, by M. de Jonquières.—Contribution to the study of Zeeman's phenomenon, by MM. Henri Becquerel and H. Deslandres. An account of some experiments on the influence of a magnetic field upon the periods of vibration of the radiations emitted by incandescent vapours.—Movements of the sensitive plant when grown in water, by M. Gaston Bonnier. The author has succeeded in cultivating *Mimosa pudica* completely immersed in water, and has studied in detail the alterations in structure and movement brought about by the new conditions of life.—On the deformation of compressed parts and the stability of large frame-works, by M. A. Bérard.—On congruences which are in several ways K congruences, by M. C. Guichardi.—New expression of the elements of an orthogonal system by *theta* functions of two arguments and their application in dynamics, by M. E. Jahnke.—On a transformation of Hamilton's equation, by MM. W. Ebert and J. Perchot.—On the deformations experienced by a solid dielectric on becoming the seat of an electric field, by M. Paul Sacerdote. The phenomena in question are shown to be deducible from the principles of the conservation of energy and of electricity.—On a problem in the analytical theory of heat, by M. W. Stekloff.—On the electric conductivity of solutions of permanganate of potassium, by M. Emmanuel Legrand. The molecular conductivity increases with the dilution, and approaches the limiting value 124 obtained by former experimenters for neutral salts at 25° C.—On multiple resonance, by M. Louis Décombe.—On the thermic mercurial ampère-meter and its industrial applications: new standard of electromotive force, by M. Charles Camichel.—Comparison of the atomic weights of hydrogen, nitrogen, and carbon deduced from physical data with their values as deduced from chemical analysis, by M. Daniel Berthelot. The author claims that the calculation of atomic volumes and atomic weights from accurate determinations of the density and compressibility allows of the confirmation and, in certain cases, of the statement with precision of the results given by chemical analysis. The results obtained by various observers in the case of the three elements mentioned are criticised in detail.—Isoquinoline and tetrahydroisoquinoline, by M. Marcel Delépine. A thermo-chemical study.—On the estimation of small quantities of carbon monoxide in air and in normal blood, by M. L. de Saint-Martin. The author, in reply to the criticisms of M. Gautier, further explains the analytical modifications introduced by him. A series of experiments are described to demonstrate the presence of carbon monoxide in the blood of animals living in large towns.—On the spectrum and the nature of neodymium, by M. Eug. Demarçay.—Action of oxidising agents on some nitrogenous bodies, by M. Œchsner de Coninck. An account of the action of hypochlorites, in presence of excess of alkali, upon amines, diamines, hydrazines, cyanic and cyanuric acids, and various alkaloids.—Combination of mercuric nitrate and trimethyl carbinol, by M. G. Denigès. The author describes the preparation and properties of a new compound, which he terms mercuroso-mercuric dimethylethylenic nitrate.—On the physiology of gentianose; its hydrolysis by soluble ferments.—Detection of wood saw-dust in flour, by M. G. A. Le Roy. The suspected sample is gently warmed with an alcoholic solution of phloroglucinol, strongly acidified with phosphoric acid. The particles of saw-dust are stained an intense carmine-red colour, while the starch and cellulose of the grain itself are little, or but slightly, affected.—On the crystalline forms of the *oligist* of Puy de la Tache (Mount Dore), by M. F. Gonnard.—On the micro-organisms of "turned" wines, by MM. F. Bordas, Joulin, and de Raczkowski. The authors have isolated and studied an organism, which they propose to term *Bacillus roseus vini* from the colour assumed by its cultivations in certain media.—Effects of the solar and lunar attractions upon the atmosphere of the northern hemisphere at each of the four phases, by M. A. Poincaré.

DIARY OF SOCIETIES.

FRIDAY, April 15.

Malacological Society, at 8.—On some New Species of Land Shells from South America: S. I. Da Costa.—Note on the Anatomy of *Resania*, Gray, and *Zenatia*, Gray: W. H. Dall.—Note on the Anatomy of *Mülleria*: M. F. Woodward.

MONDAY, April 18.

Society of Arts, at 8.—Sources of Commercial India-rubber: Dr. D. Morris, C.M.G.

Victoria Institute, at 4.30.—The Design of the Human Foot: Gerard Smith.

TUESDAY, April 19.

Zoological Society, at 8.30.—On the Breeding of the Dragonet (*Callionymus lyra*): Ernest W. L. Holt.—On the Serricorn Coleoptera of St. Vincent, Grenada, and the Grenadines, with Descriptions of New Species: Rev. H. S. Gorham.—Note on the Affinities of *Palaeospondylus gunni*, Traq.: Dr. Bashford Dean.

Institution of Civil Engineers, at 8.—Paper to be discussed: The Electricity Supply of London: A. H. Preece.

Royal Victoria Hall, at 8.30.—X-Rays: Bruce H. Wade.

WEDNESDAY, April 20.

Society of Arts, at 8.—Stage Mechanism: Edwin O. Sachs.

Geological Society, at 8.—Note on an Ebbing and Flowing Well at Newton Nottage, in Glamorganshire: H. G. Madan.—*Petalocrinus*: F. A. Bather.—On the Origin of the Auriferous Conglomerates of the Gold Coast Colony (West Africa): T. B. F. Sam.

Royal Meteorological Society, at 7.30.—Anticyclonic Systems and their Movements: Major H. E. Rawson.—Results of Observations on Haze and Transparency in 1897: Hon. F. A. Rollo Russell.

Royal Microscopical Society, at 7.30.—An Exhibition of Diatoms: H. Morland.——At 8.—On some Organic Substances of High Refractivity available for Mounting Specimens for Examination under the Microscope: H. G. Madan.—Instantaneous Photomicrography: E. B. Stringer.

THURSDAY, April 21.

Society of Arts (Indian Section), at 4.30.—Recent Railway Policy in India: Horace Bell.

Linnean Society, at 8.

Institution of Electrical Engineers, at 8.—Cost of Generation and Distribution of Electrical Energy: R. Hammond. (Continuation of Discussion.)

Chemical Society, at 8.—The Carbohydrates of Barley Straw: C. F. Cross, E. J. Bevan, and Claud Smith.—Isomeric Bornylamines: Dr. M. O. Forster.—Some Derivatives of Benzophenone: Dr. F. E. Matthews.—Researches on Camphoric Acid: Dr. S. B. Schryver.—Ballot for Election of Fellows.

BOOKS, PAMPHLETS, and SERIALS RECEIVED.

Books.—The Barometrical Determination of Heights: F. J. B. Cordeiro (Spon).—A Manual of General Pathology for Students and Practitioners: Dr. W. S. Lazarus-Barlow (Churchill).—Practical Radiography: A. W. Isenthal and H. S. Ward, 2nd edition (Dawbarn).—Elementary Chemistry: T. A. Cheetham (Blackie).—Synopsis Characearum Europaearum: Dr. W. Migula (Leipzig, Kummer).—Accounts of the Trade carried by Rail and River in India in the Official Year 1896–97 and the Four preceding Years (Calcutta).—Notes on Observations: S. Lupton (Macmillan).—An Elementary Course of Physics: edited by Rev. J. C. P. Aldous (Macmillan).—Essays on Museums, &c.: Sir W. H. Flower (Macmillan).

Pamphlets.—Some New Indo-Malayan Orchids: G. King and R. Pantling (Calcutta).—A Simple Guide to the Choice of a Photographic Lens: T. R. Dallmeyer (J. H. Dallmeyer).

Serials.—Knowledge, April (High Holborn).—Bulletin of the American Mathematical Society, March (N.Y., Macmillan).—Transactions of the Astronomical and Physical Society of Toronto, 1897 (Toronto).—Observatory, April (Taylor).—Atlantic Monthly, April (Gay).—Journal of the Sanitary Institute, April (Stanford).—Zeitschrift für Wissenschaftliche Zoologie, lxiii. Band, 3 Heft (Leipzig, Engelmann).—Materials for a Flora of the Malayan Peninsula: Sir G. King, No. 10 (Calcutta).—History of Mankind: F. Ratzel, translated, Part 25 (Macmillan).—Psychological Review, Monograph Supplements, Vol. 2, No. 2 (Macmillan).—Reliquary and Illustrated Archæologist, April (Bemrose).—Mind, April (Williams).

THURSDAY, APRIL 21, 1898.

A NEW DEPARTURE BY THE RAY SOCIETY.

The Tailless Batrachians of Europe. Part i. By G. A. Boulenger, F.R.S. Pp. 210. (London: The Ray Society, 1897.)

THE publication of this elegant treatise marks an event in the history of the Ray Society upon which its members, so long content with a diet of insects, are to be heartily congratulated. Of the 210 pages of the work, 121 are devoted to an "Introduction" in which the classification, taxonomic characters, skeleton, viscera, habits, and reproduction of the Batrachia Ecaudata are successively dealt with on broad lines, special sections being added on hybrids and geographical distribution. The remaining ninety pages are devoted to a systematic treatment of the Discoglossidæ and Pelobatidæ (*i.e.* of eight of the twenty European species which the author admits), in which specific diagnoses, geographical varieties, the skeleton, habits, eggs, tadpole, and habitat, are categorically dealt with in popular but trustworthy terms. This arrangement has involved the author in an amount of repetition, but owing to the judicious placing of the seventy-seven processed drawings which adorn the work, all suspicion that this may be needless disappears, text and illustrations being found to supplement each other in accordance with a well-conceived plan. In addition, there are two maps and ten plates, six of the latter being admirable examples of the chromo-lithographer's art, of which it is praise sufficient that the author declares them to have fully satisfied his aspirations. The classification adopted is that of Cope, as emended by the author in the course of five-and-twenty years' experience, its leading feature being the grouping together of the genera *Alytes*, *Bombinator*, and *Discoglossus*, as a family (the Discoglossidæ) having well-defined and lowly affinities, which all recent investigation has confirmed. Mr. Boulenger is the foremost among the world's younger herpetologists, and in knowledge of his experience acquired during the custody of the world's greatest collection of reptiles and batrachians, of his devotion to his calling, and of his well-tried judgment, expectation ran high on the announcement of the work. It has been realised; suffice it to say that the book marks an epoch in the popularisation of zoological science, and must take its place in history beside the memorable works of Rösel von Rosenhof and Spallanzani, "Die in Deutschland lebenden Saurier" of Leydig, and others of the kind. It abounds in original observation and teems with enthusiasm, and without it no zoological library worthy the name can be complete.

The section dealing with the viscera is somewhat less satisfactory than the rest, but it is fair to the author to remark that he purposely excludes a general description of the "internal soft anatomy," and confines his attention to the "structure of the lungs and urogenital apparatus," which he regards as "of special importance from the point of view of the systematist." He in this way leads up to his morphological *tour de force*, in which (Sections 9 and 12 more particularly) he deals in an altogether masterly manner with the breeding habits and metamorphosis, earlier published papers upon which have rendered him famous. And in this connection it is particularly noteworthy that an observer of such ripe experience should pronounce against the popular ideas concerning the significance of the tadpole stage. Believing, as we do, that the conception of the frog's climbing up its own phylogenetic tree is erroneous, and that in the recognition of characters expressed in the term "derotrematous," in respect to which condition some living Batrachia are veritable fishes, far-reaching generalisations founded on the piscine resemblances of the tadpole are superfluous and have been misleading, we hail with much satisfaction the author's assertion that "larval forms such as the tadpoles are outside the cycle of recapitulation."

The only call for revision which we note is in the terminology, and that more particularly anatomical. The usage of the terms "epicoracoid" and "sternum" is regrettable, since the former, as an independent element of the shoulder-girdle, has no existence in the Batrachia, and in them the latter is known to be no derivative of the costal skeleton. "Abdominal cavity" is equally inexpressive, and the application to the vertebræ of the term "dorsal"[1] (still so barbarously retained for the thoracic of the amniota) is wrong. The description of the os cruris on one page as the "crus or tibia" and on another as the "tibia-fibula," like that of the investment of the ovum as a "gelatinous envelope" and a "sticky mucilage," is contradictory; while the reference to the fronto-parietals of *Pelobates*, on p. 35, is incomplete, by lack of insertion after "in" of the words "the adult." "Articulary balls" is amusing in its unconventionality, and "adhesive sub-buccal apparatus" is needlessly involved. The description of the so-called external type of vocal-sac as occurring in *Rana*, involving "a diverticulum of the mylo-hyoid muscle" and the said "slits at the sides of the throat," is calculated to convey a wrong impression of the facts, and error appears most seriously to have crept into the account given of the genital ducts of the males, in a manner alluded to below, for which it will be seen the author is little to blame.

The above-named are but trivial defects and unfortunate modes of expression, which in no way detract from the merits of the book. The author in his preface deplores the fact that few persons share with him a fondness for the Batrachia Ecaudata, and it must be admitted that, with the Teleostean Fishes and other groups of animals forming culminating series in definite lines of modification, these have been largely neglected by recent investigators, who, fascinated by the lowly and more generalised, have put them aside as useless in their specialisation. The study of the Teleostei is now setting these persons right on fundamentally important topics, and we claim that the remarks appended to this review justify the assertion that in the study of the despised Anura there lies the settlement of that which is to-day one of the most vexed questions concerning the genital ducts of the vertebrata. And tempted thus to speculate upon what remains to be ascertained about mere frogs and toads, the mind reverts to their mechanism of accommodation for vision within and without the water, our knowledge concerning which is an absolute blank. If we may judge by analogy to the inanimate, displacement of the lens of an altogether remarkable order must take place, and there is thus opened up a line of investigation of absorbing interest alike in its morphological, physiological, and physical aspects, in which, to say the least, there probably lies the explanation of the remarkable series of accessory eye-muscles which these animals possess.

---

[1] "Presacral" is the only term by which these can be accurately described in the Batrachia.

That a great deal remains to be done in the study of these familiar creatures is certain. The author has produced a masterly treatise upon their classification and distribution, upon which he is now a leading authority. He deals with a subject historically associated in a prominent manner with the labours of English-speaking zoologists, and tells us that he will be content if those who use the book may derive from the perusal of its pages one-tenth of the pleasure it has given him to write them. His preface, in which this sentiment occurs, is positively infectious in its enthusiasm, force of personal example, and love of science for its own sake; and neither he nor we could desire more of his book than that it might stimulate to action some one who should in turn succeed him as a foremost authority upon the group of animals with which it deals.

Concerning the vestigial portions of the urinogenital apparatus above referred to, the author, relying only upon macroscopic characters and following Spengel, has described the duct which in *Alytes* receives the vasa efferentia as Müllerian; and he regards the vesicula seminalis in all forms as a derivative of that. He omits mention, however, of the vestigial Müllerian duct of the male *Rana*, which, though exceedingly delicate, is usually present; and this is the more regrettable, since Marshall proved microscopically that it skirts the outer border of the vesicula as an independent tube. The relationships of the vesicula to the so-called "ureter" in *Rana*, and to the presumed Müllerian duct in *Alytes*, the alleged homology of which has been challenged, are thus seen to be identical, wherefore the latter would appear to represent the Wolffian duct proper, and the so-called "ureter" of the Anura either a specialised portion of that, or an independent duct arising from the kidney, as might well be from the condition in *Alytes* and some Urodela. Comparative embryologists will not need to be reminded that a precisely similar difficulty besets the interpretation of the corresponding parts in the Elasmobranch fishes, and as concerning the Anura more particularly the whole matter, anomalous to an unparalleled degree on the Spengelian interpretation, apparently harmonious and exceptionally instructive by extension of Marshall's observation, demands renewed microscopic inquiry. Indeed, to the present writer it has long appeared that the male genitalia of *Alytes* and *Discoglossus*, as here interpreted, conform to a type transitional between that of the Urodela in which a fully-developed Wolffian body, differentiated into a sexual and a renal portion, is present, and of the higher Anura, in which the homologue of the renal part receives the vasa efferentia, and to justify the conclusion that the latter condition is secondary and associated with the suppression of the sexual part. And if this be so, an additional argument will have been furnished for the lowly affinities of the Discoglossidæ.

G. B. H.

PREHISTORIC CIVILISATION IN EGYPT.

Recherches sur les Origines de l'Égypte. Ethnographie Préhistorique et Tombeau Royal de Négadah. Par J. de Morgan. Avec la collaboration de MM. Wiedemann, Jéquier, et Fouquet. Pp. x + 395. (Paris: Leroux, 1897.)

THE large section of the scientific public which is interested in prehistoric remains will, we are sure, cordially welcome the second part of M. de Morgan's work on "Les Origines de l'Égypte," which is now before us. Every reader of the first part waited, we fear with some impatience, for the supplementary facts which were known to be forthcoming; and now that they are in our hands, it is more possible to judge of the general effect of M. de Morgan's recent discoveries upon the sciences of archæology and anthropology. For some years past the natives of Upper Egypt have been offering numbers of curious objects for purchase to the tourist and wandering Egyptologist, and the said objects were so remarkable from artistic and other points of view, that more than one archæologist have pronounced them to be forgeries. That these objects came from several different places in Upper Egypt was quite certain, but it was hard to believe the fact, and most people, whatever they said, privately thought the statements of the natives to be unbelievable.

M. de Morgan was the first to find the solution of the difficulty, and now he has triumphantly proved that these strange objects do really come from a number of sites which extend along the Nile Valley from Cairo on the north to Wady Halfa on the south, and that they represent the remains of a people who occupied Egypt before the Egyptians who have hitherto been known to us from inscribed statues, temples, &c. In the second chapter of the present volume of his work he gives a list of these sites, and it may be considered the most important section of his book; it is much to be hoped that now circumstances have obliged him to transfer the field of his labours to Persia, others, whether they be English or French, may take steps to examine by means of systematic excavations the sites of which he has given us such a full list.

But though M. de Morgan has not been alone in making researches concerning the history of the remote period in which these sites were occupied, and though Messrs. Petrie and Amélineau have collected much information from their excavations at Amrah, Ballas, and Nakada, it must not for one moment be imagined that all the questions connected with the prehistoric people of Egypt can be answered, or all difficulties solved. Nor can it be said whence this people came, or when they first occupied their stations in the Nile Valley; at present it is difficult even to find a name for them which will satisfy both M. de Morgan and Mr. Petrie. M. de Morgan, basing his opinion upon anthropological evidence adduced by Dr. Fouquet, as much as upon the archæological evidence which he himself has carefully sifted, has come to the conclusion that the people whose remains he has found are as old as any race known in the world, and that, in any case, they are the earliest inhabitants of Egypt. On the other hand, Mr. Petrie calls them the "New Race," which appellation, viewed in the light of the evidence given in M. de Morgan's book, is clearly wrong, and shows that Mr. Petrie did not understand the facts of the case.

According to M. de Morgan the word "Egyptian" signifies the man who migrated from Asia to Egypt, whose civilisation was peculiar to himself, and whose ethnic history is still unknown. Between him and his predecessor, whom we may call the aboriginal inhabitant, he draws a sharp distinction both mentally and morally, and the former was mesaticephalic and the latter dolichocephalic. It is important to note that the *indigènes* had smooth and fair hair, and that they belonged to the white race; thus the old theory that the Egyptians were of negro origin receives another blow, and incidentally it is quite clear that the Cush referred to in the Bible as the home of the Egyptian is not Ethiopia. In the chapter on the indigenous peoples of Egypt we have a most useful account of the various objects which have been found in the prehistoric sites, well illustrated by scores of woodcuts which will prove invaluable to those who have not the opportunity of studying the originals, and at the end is given a good account of the various methods of burial employed by the *indigènes* of Egypt.

In the earliest times the dead were buried without any attempt being made to mummify the body or to strip the bones of their flesh. Later, the flesh was stripped from the bones, which were then buried, frequently in great disorder; sometimes the body was simply hacked in pieces so that it might be packed easily in a small space. Still later, an attempt to preserve the body by mummification was made; for Dr. Fouquet has found traces of bitumen in the bones which he has examined. In the earliest tombs no metal objects have been found, but of those in which no instruments of iron and bronze have been discovered, the famous tomb at Nakada which M. de Morgan first excavated, and has described in the fourth chapter, is the best known example. It is, of course, quite easy to see from the remains of offerings found in the prehistoric tombs that the belief in a future life of those who made them was both well established and widely known. And if they believed in a future life it seems that they must of necessity have believed in a divine power, and to have the superstitions which take the place of religion among early peoples. The abominable practice of cannibalism which Mr. Petrie attributed to his "New Race," finds no support in the account which M. de Morgan has given of this people, and we agree with Dr. Verneau, who in discussing this subject says—

> "Les faits allégués à l'appui de cette assertion s'expliqueraient tout aussi bien si l'on admettait simplement un décharnement à l'air libre, précédant l'ensevelissement définitif."

Mr. Petrie's sensational discovery therefore falls to the ground.

Space will not allow us to discuss the objects which M. de Morgan found in the tomb of Nakada, much less to refer to the interesting deductions made by M. Wiedemann from them; it must suffice to say that quite new light is thrown upon many well-known facts, and that many of our preconceived notions must be abandoned. Of special interest to the anthropologist is Dr Fouquet's minute description of the skulls of the *indigènes* of Egypt; the careful measurements, too, will be invaluable to him. Neither M. de Morgan nor Dr. Fouquet attempts to assign a date to the occupation of the land of Egypt by this people, and no guess is made at the length of its duration.

Though M. de Morgan's last work does much to settle the difficulties which his own discoveries have raised, many questions must, we fear, for some time remain open. But to him all students owe a big debt of gratitude, both for the careful way in which he has collected and stated his facts, and for the zeal with which he carried out his excavations; his work is of peculiar value from the fact that he never forgets his task as an expounder of facts so far as to become an advocate. The mere Egyptologist would have misread the evidence of the prehistoric graves because he never takes the trouble to realise that a good Egyptologist is not necessarily a good archæologist, and we must be thankful that for once the right work fell into the right hands. All will, however, regret that the French Government has removed M. de Morgan from Egypt to Persia, especially as they did so at the time when he was doing his best work.

A COUNTY FLORA.

The Flora of Berkshire. By George Claridge Druce. Pp. cxcix + 644. (Oxford: Clarendon Press, 1897.) [Published 1898.]

THIS volume is worth a review, for it has merits found in but few "Floras," and failings common to many.

In 1886 Mr. Druce published "A Flora of Oxfordshire"—a flora, except for the inclusion of some account of the lower plants, of the very ordinary type. In his second flora, while omitting the lower plants except *Characeæ*, he introduces in his critical notes on species a new feature. Every variation has a claim on the botanist's attention; and where can local varieties be better considered than in a local flora? It is a good feature in the book. And, further, the mania for names or for giving prominence to names does not offend. The varieties are usually mentioned in these notes in a way which gives an appearance of proportion to the enumeration, and so do not appear—undefinable gradations as they often are—in series like so many milestones along the road.

A county flora must always be considered from the dictionary standard. The main body is of necessity a work of reference. Viewed in this light, we find in the "Flora of Berkshire" merits and demerits. The division of the county into geographical areas is satisfactory, much more so than in the "Flora of Oxfordshire," where they are very unequal. In a level region, such as that of our Midland counties, there are no natural areas, unless they be made by the soil. To follow the outlines of the various formations, as Babington well did in his "Flora of Cambridgeshire," would for Berkshire be a difficult task; and Mr. Druce may not have done amiss in defining his regions by drainage. The result of his division is that every region contains some chalk, and consequently some of its characteristic vegetation.

An original dictionary is aggravating; and Mr. Druce is unwise in choosing, by his changes in nomenclature, to publish such. Of all places, except perhaps a seedsman's catalogue, such alterations could not be more out of place. And when he selects to give *Potamogeton* two genders he becomes pedantic. To expect a man with more common sense than leisure to inquire before writing the name of a species of this genus whether its author made it masculine or neuter, is to proffer him a fetter of a nature as galling as purposeless. It may be safely said that this is a demerit possessed by no other English county flora.

In the next place, a county flora must be considered as a geographical study. Great pains are usually taken to get together accurate facts (and this flora is no exception); but the builder tips up his bricks and mortar at your door, leaving the building to your own architectural fancy. As long ago as 1863, in Baker's "North Yorkshire," an admirable model was set, but no one has followed in the same lines. Mr. Druce in the introduction gives a long description of his districts, and long lists of the noteworthy plants, but in the summary he fails to point out any connection between these; he points out the soils of the county well—perhaps not so well as in Pryor's "Hertfordshire Flora"—but fails to summarise their effects on the plant formations; he has pointed out the deforesting of the land, but hardly notices its effects; and he has given us agricultural returns, and passes unnoticed the effects of agriculture. Surely such things should be the crowning of such a book—a bringing into one view the long arrays of facts which have gone before. It is a fault of most floras that they are wanting in this.

This "Flora of Berkshire" forms a thick volume of more than 800 pages; and it is not free from irrelevant remarks. For instance, the fossil shells of the Lower Greensand (p. xxxi) have no bearing on the subject; the history of the "Imp" stone (p. xlii) is out of place; most of the matter on river drainage (pp. xlvii–liii) is of little use; to be informed that the late M. A. Lawson compiled a MS. index to Jaeger's "Adumbratio" (p. clxxvii) is not of interest, and but poor salve to one who needs use those two cumbersome volumes; nor does it in the least benefit us to be told that Mr. Druce has been unable to elicit any reply from certain critical botanists.

Caution, too, is sometimes left behind. That *Elodea* is dying out by reason of the absence of the ♂ plant (p. 465) is merely a conjecture. A little knowledge of recent literature should have shown that *Nepeta Glechoma* var. *parviflora* (p. 402) is merely a condition. In fact, Mr. Druce's "Flora of Berkshire," founded on so much labour, deserved a careful revision before it went to press, and did not get it. It may rank with our best county floras in some ways; but most of these are far from approaching a high scientific standard. There is a tendency now to aim at more ambitious works than catalogues of "Phanerogams." The comprehensiveness of Purchas and Ley's "Flora of Herefordshire," the notice of the past vegetation of the peat in Hind's "Flora of Suffolk," the scattered biological notes of Scott-Elliot's "Flora of Dumfriesshire," and the critical remarks of Druce's "Flora of Berkshire" are good signs, which we hope may lead to better things.

I. H. B.

AMONG THE ISLANDS OF THE PACIFIC.

Wild Life in Southern Seas. By Louis Becke. Crown 8vo. Pp. viii + 369. (London: T. Fisher Unwin. 1897.)

THE author of "Pacific Tales" and "By Reef and Palm" stands in no need of introduction either to the reader of fiction, or to the more serious-minded who seek for information upon a part of the world where the "personally-conducted" tour is as yet unknown. Mr. Becke, in virtue of his twenty-six years of wandering among the islands of the Pacific, has made himself an acknowledged authority upon most of them, from the Carolines to the Paumotus, and now that Major Sterndale is no longer with us, is probably better qualified to speak of this region as a whole than any person now living, though there are doubtless others whose knowledge of individual groups is more extensive. The volume before us is upon the same lines as "By Reef and Palm," a collection of reminiscences *per ci per là*, rather less full of deeds of bloodshed, perhaps, than the latter volume, and containing more of interest to the naturalist and ethnologist, but at the same time possibly not devoid of fiction, or at least of fact and fiction commingled. Some of the articles seem familiar to us; one at least, upon *Birgus latro*, has appeared in the columns of the *Field*.

The volume is one which will appeal especially to the sea-fisherman who has tasted of the delights of reef-fishing in Pacific waters, for half a dozen or more of the articles are devoted to this sport in one shape or another. The abundance of fish is not less remarkable than their variety. Mr. Becke tells us that in the Ellice group he has seen as many as twenty canoes loaded to sinking point in less than an hour; while, as for size, the *takuo*, a large species of albacore, reaches the weight of 120 lb. and more. Shark-fishing is no very novel amusement, perhaps, but catching flying-fish is a sport not so widely practised, and Mr. Becke's description of it is a vivid one. He has also done well in putting together his sketch of the history of whaling in the South Seas.

No new light is thrown upon the curious stone buildings and fortifications which exist over the length and breadth of the South Pacific, and have for so long puzzled archæologists, though Mr. Becke speaks of what are probably the most extensive of all—those on Espiritu Santo. Some interesting facts concerning population are given. It has now been known for some time that the extinction of these island peoples in consequence of the advent of the whites, formerly regarded as an immediate certainty, is not only not impending, but is never likely to occur, except by the process of fusion—that the census minimum has been reached, and that steady increase is the rule rather than the exception. Funafuti, the island lately visited by the coral-boring expedition, is a good example of this. About sixty or seventy years ago its population was estimated at 3000; in 1870 Mr. Becke counted only 160; and now it is said that there are over 500 inhabitants. Nanomaga, too, can scarcely be quoted as an example of the extinction of the native, for here, in an area of a square mile, we find a population of more than 600—a density only equalled by that of some of the islands of the neighbouring Gilbert group. It is to be hoped that the author of "Wild Life in Southern Seas" may some day put his knowledge of the islands into more regular and scientific form. F. H. H. G.

OUR BOOK SHELF.

Mediterranean, Malta, or Undulant Fever. By M. Louis Hughes, Surgeon-Captain Army Medical Staff. Pp. xi + 232; figs. iv.; tables xv.; charts xx. (London: Macmillan and Co., Ltd., 1897.)

THE book before us is an exhaustive monograph upon an apparently, up to the present, neglected variety of continued fever, viz. Mediterranean or Malta fever. The author, at the beginning of the monograph, gives reasons why this fever should be regarded as a definite specific disease—distinct, on the one hand, from malarial and, on the other, from enteric fever, and suggests that it should in future receive the name of undulant fever. The term Mediterranean, Gibraltar, or Malta fever is, according to him, misleading, as apparently ascribing to the disease a geographical limitation which it does not possess.

In Chapter ii. a discussion will be found of the bacteriology of the disease. The author's observations, so far as the presence of a definite micro-organism, and the artificial production of the fever in monkeys are concerned, confirm Bruce's earlier results. Chapter iii. is devoted to symptomatology, and concludes with a description of the usual complications and sequelæ. In Chapter iv. the author discusses fully differential diagnosis, prognosis, and morbid anatomy. The final chapter is devoted to the consideration of prophylaxis and treatment. Two good indices conclude the volume.

The work will doubtless be of great service to those who are engaged in military or civil practice at Gibraltar or Malta, and must further be regarded as a valuable addition to the literature of continued fevers.

F. W. T.

Lehrbuch der Vergleichenden Mikroskopischen Anatomie der Wirbelthiere. Zweite Teil, Schlund und Darm. Von. Dr. Med. Alb. Oppel, a. o. Professor an der Universität Freiberg i.B. Pp. 681, with Plates. (Jena: Gustav Fischer, 1897.)

THIS volume is a worthy successor to its predecessor on "The Stomach," published in 1896, and we have nought but praise for it. At first sight it would appear well-nigh impossible that two such works could be successfully compiled in so short a time; but there is internal evidence that the book bears a direct relationship to a series of papers which its author has published during the last eight years, and that its preparation has been a prolonged labour of love. The present volume opens with a dissertation upon the structural plan of the alimentary canal and its derivatives, extending to thirty-one pages; and in the rest of the book the ordinarily recognised regions of the intestine, and the œsophagus, are successively dealt with in an exhaustive manner, structure and function being alike considered. The work closes with a 36-page alphabetical record of literature arranged according to authors' names. The mode of treatment of the subject, like that of the preceding volume on the stomach, is thoroughly systematic and logical; and while the pages of the book bristle with references to original authorities, its style is nowhere pedantic. Though termed a text-book, it is an exhaustive work of reference such as we believe the advanced scientific text-book of the future must become. There are 343 admirable text illustrations and four exquisite plates, well worthy the text and the immense labour its author has bestowed upon it. We note one or two omissions, as, for example, of all mention of the intestinal valve in the Teleostei (*Cheirocentrus*) and of Huxley and Parker's observations upon the cœcal and colic valves of *Lepus*. The fuller paper by Laguesse might have been referred to, as might the observations of Mazza and Perugia upon the rectal glands of *Chimæra* and other matters which could be mentioned. All that is really important, however, is recognised. The work fills a gap in our literature, and to its author students and teachers stand alike indebted for a masterly treatise which will long remain the standard book of reference upon the subject with which it deals.

Spectrum Analysis. By John Landauer, LL.D. Authorised English edition by J. B. Tingle, Ph.D., F.C.S. Pp. 239 + x. (New York: Wiley and Sons. London: Chapman and Hall, 1898.)

THAT there is a real need for a fairly comprehensive text-book of spectrum analysis of moderate size will be acknowledged by all who have occasion to teach the principles of the subject, or to employ its methods for analytical purposes. To meet this need appears to be the object of the book before us, though it does not claim to be exhaustive. The treatment of the subject is historical throughout, and there is a great number of useful references to important memoirs, while particulars of the spectra of elements and compounds occupy nearly one-third of the volume. As a general text-book of the subject, apart from its astronomical applications, the book has much to recommend it; but it leaves a great deal to be desired as a guide to the practical details of spectroscopic work, which, as the translator remarks, "furnishes so many opportunities for an excellent training in accuracy of observation and manipulative skill." The lack of the practical touch is frequently indicated. In the table of magnesium lines (p. 143), for example, the lines of the arc and spark spectrum are grouped together, and the omission of the most striking line of the latter at λ 4481, possibly for the reason that it is all but invisible in the arc, might cause much loss of time to a student who happened to observe this line and attempt to ascertain its origin. Again, there are no instructions for photographing spectra, although in the majority of cases this is by far the best method to adopt in practice. Least satisfactory of all, the whole subject of comparing observed with tabulated spectra is far too cursorily dealt with to be of real value to the practical student.

In various theoretical matters, such as the relationship of the lines of an element to each other, the subject-matter is well up to date; but, as already hinted, the astronomical applications are scarcely touched upon.

The illustrations call for little remark. Most of them are well-worn, and we especially regret that the author has seen fit to prolong the life of the feeble map of the solar spectrum on p. 187, which so inadequately represents Fraunhofer's beautiful original.

Tabellarische Uebersicht der Mineralien nach ihren krystallographisch-chemischen Beziehungen geordnet. Vierte Auflage. By P. Groth. (Braunschweig, 1898.)

THE fourth edition of the well-known tables of the Munich Professor closely resembles its predecessor in appearance and in general character, but has in reality been considerably modified. Each well-defined mineral group is now introduced by a general discussion of the chemical and crystallographic relationships, in place of the notes appended to each group in the earlier editions; and the crystal class to which each mineral belongs is defined. Thus the book, while preserving the form which is now so familiar to every student of mineralogy, is in reality much more of a treatise on mineral chemistry than it was before. In fact, it may be regarded as the most useful text-book on this subject available for a student. The researches of Penfield and of Clarke have thrown a flood of new light upon the chemistry of minerals, and Prof. Groth is, as is well known, never slow to incorporate the latest results of science in his books.

These tables are indispensable to the student, and of immense use to the systematic mineralogist: to the latter especially in those passages which express the critical views of an author of unrivalled experience and judgment upon minerals of obscure composition.

The following examples, chosen almost at random, will suffice to illustrate the modifications which have been introduced into the old classification. Pyrrhotite is now FeS, and is placed in the Wurtzite group; Lorandite, the new sulpharsenite of thallium, is placed with Miargyrite; Ilmenite has been removed from the Hæmatite group of oxides, and is classed with Pyrophanite as a titanate of iron, in consequence of recent observations by Penfield.

But it is needless to multiply examples. The book should be the handy companion of every mineralogist. It is only necessary that in this, as in former editions, the reader should bear in mind that rational formulæ in mineralogy are never free from the taint of speculation.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

Sub-Oceanic Terraces and River Valleys of the Bay of Biscay.

Will you allow me to add to my communication, which appeared in Nature of March 24, regarding the results of investigations carried out by means of the Admiralty charts beyond the coast of the British Isles, a still further statement regarding the Bay of Biscay? The results are not less remarkable and suggestive of great changes of level than are those indicated by the soundings to the west of the British Isles, which I hope to describe in full at the meeting of the Victoria Institute on May 2. We have the same general physical contours: first, the Continental shelf, or platform, stretching out for a distance of over 100 miles along the northern edge of the bay, but narrowing southwards till along the coast of Spain it contracts to an average breadth of twenty to thirty miles. At its outer margin the shelf breaks off at the 200-fathom line in a grand escarpment, continuous with that of the British platform, and descending with a more or less steep descent to somewhat over the 1200-fathom line. Off Cape Ortegal the escarpment is almost precipitous, for the total descent of 7000–8000 feet is effected within a horizontal space of about four miles; from the base of the escarpment the ocean-floor, formed of calcareous ooze, stretches gradually away to depths of 2600 fathoms and upwards. The escarpment forms the natural boundary between the region of *Globigerina* ooze and the Continental platform of sand, mud and gravel with shells.

Lastly, the old channels of several of the river valleys can be distinctly traced when they approach and intersect the grand escarpment. This is remarkably so in the case of the Loire, the Adour, the Las Cubas and Caneiro rivers. The Adour passes out to the deep ocean through a continuous deep cañon or gorge of 100 miles in length—marked on the Admiralty chart at its upper end as "Fosse de Cap Breton." At a distance of thirty miles from the coast the bed of the cañon is about 3174 feet below the general level of the Continental shelf, and at a distance of sixty-two miles it descends to a depth of about 5442 feet below the same level. The cañon itself can be distinctly traced to the depth of 9000 feet (1500 fathoms), where it opens out on the oceanic floor, representing the feature known by American geologists as "the base level of erosion"—in other words the limiting depth of river-erosion at the time when the land was elevated, and indicating the extent of the elevation as compared with the ocean level of the present day. The "embayments" of the other rivers mentioned can be traced to about the 1200-fathom contour. Such concurrence of evidence as regards the great up-lift, presumably reaching its maximum at the commencement of the Glacial Epoch, is conclusive in its testimony. The British and Continental platform was probably referable to the Mio-pliocene period.

Edward Hull.

April 19.

Dust Fog in the Canaries.

In amplification of the notice published in Nature concerning the dust shower encountered by the *Roslyn Castle* off the west coast of Africa, I have the honour of sending you the following description of the phenomenon as experienced in the city of Laguna (Teneriffe), that I have received from Prof. Calvo, keeper of the Meteorological Station. I send also a summary of the meteorological register.

Augusto Arcimis.

Instituto Central Meteorológico, Madrid, April 14.

From the first hours of the evening of February 15, there was observed a sensible but light fog; neither the strength of the wind (E. gentle breeze) nor any other phenomenon indicated that the supposed condensed vapours could be African dust transported by the air. As the night advanced, the force of the wind increased, until it reached the value of a moderate gale. At about 5 a.m. on the 16th, some large drops of rain fell, but were inappreciable in the rain gauge. For a very short time the wind subsided, by and by becoming again a gentle breeze during the day and blowing due E. The fog became more dense, causing depression and a disagreeable feeling produced by its dryness. The sun, on account of its light being pale and feeble without the usual rays, was confounded with the moon; and it reminded one of the light of a voltaic arc seen through a frosted glass. The flame of a match appeared with a very marked violet hue. The drinking waters became salty and coloured as by oxide of iron. The dust was grey and extremely fine, and deposited itself on every object.

On February 19, from the early morning the sky was again clear and transparent, and the wind was blowing from the N. and N.W.

THE PHLEGRÆAN FIELDS.

THE fired rocks and hills of volcanic origin stand in so striking a contrast to those of aqueous origin, that they have exercised a very powerful influence on the thoughts of man in all ages. Frequently associated with such formations are the phenomena which we are accustomed to refer to as volcanic—"burning mountains," boiling springs, gaseous exhalations, terrifying noises—all shrouded with a mystery which demands explanation. Even in a locality in which the volcanic fires have been extinguished or have long remained quiescent, the peculiar configuration of the ground often keeps alive the tradition of former outbursts of subterranean fire, and the tradition usually supplies the explanation of the configuration. The ancient Romans, long before the awful catastrophe of A.D. 79, seem to have been quite aware that Vesuvius had not always been in a condition to support the rich cultivation which covered its slopes in their day. It is only in rare cases that the inquirer is rewarded by finding that the history of a heap of burnt soil is preserved; more often he will hear vague stories of the direful effects of prehistoric struggles of Cyclops or other mythological monsters.

In a recent research[1] I have endeavoured, by examining the marks with which the Phlegræan Fields are scored, like a much over-written palimpsest, to collect materials for a history of the alterations which the surface of the country has undergone. Within the Phlegræan Fields, west of Naples, only two volcanic structures have been formed within the historical period. For trustworthy information respecting all structures but the Monte Nuovo and the lava stream from the Solfatara we are entirely dependent upon the facts collected by the geologist and the geographer. In my work I was chiefly guided by the desire of estimating how far the existing superficial configuration or morphography of a volcanic region is an indication of the past history of its development. With this end in view purely topographical features, selected according to certain principles, were studied, and from them a theory of their origin and relative age was constructed. The results obtained by the method admit of being tested by the results of geological research whenever the latter is possible.

The importance of a method which will yield information respecting the past history of a volcanic country from a mere superficial examination is very considerable. The volcanic regions of the sea-bottom and of the moon are alike inaccessible to the stratigraphical geologist. The only kind of information obtainable is that respecting the superficial configuration; and therefore it is of the greatest importance that the value of a method which will enable us to utilise this information, in reading the records of the past, should be carefully estimated by experiment within the sphere of the geological critic.

The Phlegræan Fields are well suited for the trial of such a method, because within a small area the face of the country records the results of long-continued volcanic activity and of denudation both by sea and rain. Within an area of not much more than fifty square miles are collected the assemblage of volcanic vents and crater walls, the presence of which distinguishes the Campi Flegrei from the adjoining level plains of fertile volcanic soil of the Campagna Felice, stretching right away inland to the limestone slopes of the Apennines.

By far the most important topographical features within this region are composed of loose ashes or of compacted tufa. Lava-streams or heaps of lava characteristic of so many other volcanic regions cover but a small part of the surface of the country at the present day; in the future, no doubt, their harder, more resistent qualities will cause them to stand more prominent when the forces of denudation have removed the superincumbent layers of more readily erosible tufa.

Many of the hill forms are readily reducible to the simple type of a volcanic crater wall surrounding a crater, such as is naturally formed by fragmentary materials ejected from a vent and allowed to fall uniformly around that vent. In the Phlegræan Fields there are five almost perfect examples of such volcanic ring walls. Of these, Monte Nuovo is still to be seen in much the same condition as it was immediately after its eruption in September 1538. The Fossa Lupara, Solfatara, Astroni and Cigliano are hardly less perfect examples of typical volcanic craters. The topographical aspect of all is identical. In each a crater is entirely surrounded by an almost circular wall, which has a steep and sometimes precipitous crater-slope on the inside, but a more gradually inclined cone-slope on the outside.

Fig. 1.—Crater of Astroni from the North-East. In the distance is part of the crater wall of Archiagnano culminating in the Torre Nocera.

In addition to these hills, which are volcanic cones of the first rank of symmetry and preservation, there are others which are not less certainly volcanic cones produced in the same way, but which have had their symmetry marred by the removal of their flanks, either by marine erosion or by destructive eruption from an adjacent volcanic vent. The walls of the craters of Capo Miseno, Porto Miseno, Bacoli, Campiglione and Nisida, have all been more or less removed on the side turned towards the sea, and, with the exception of the Campiglione crater wall, are still being eroded away at the present time. The craters of Porto Miseno and Nisida are submerged, and being in communication with the open sea by breaches in their walls, afford good harbours for small vessels. The floors of the other craters are above sea-level. On the other hand, the crater walls of the Fondi di Baia, Lago d'Averno, and the two outer crater rings of the Cratere di Campana, have been partially obliterated by outbursts from other volcanic vents on or near their periphery.

[1] "The Phlegræan Fields." By R. T. Günther. (*Geographical Journal*, 1897, vol. x. pp. 412–435, and 477–499, with 8 maps and 15 figures.)

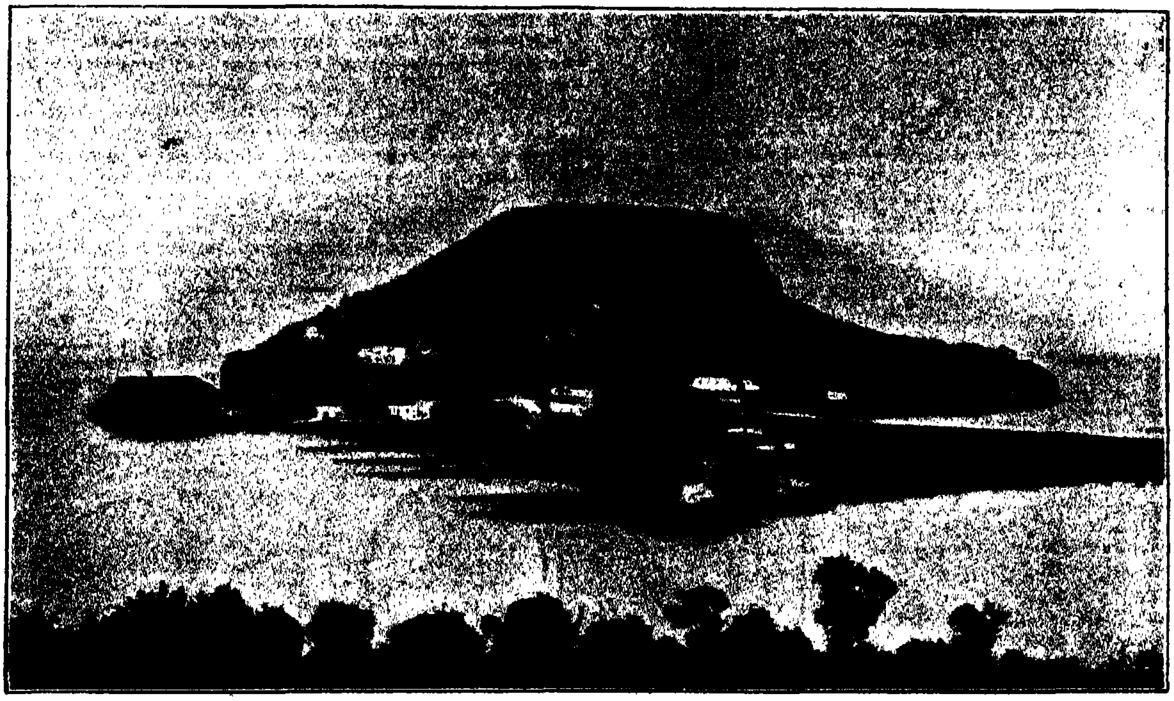

FIG. 2.—Capo Miseno from the Northern side of Porto Miseno.

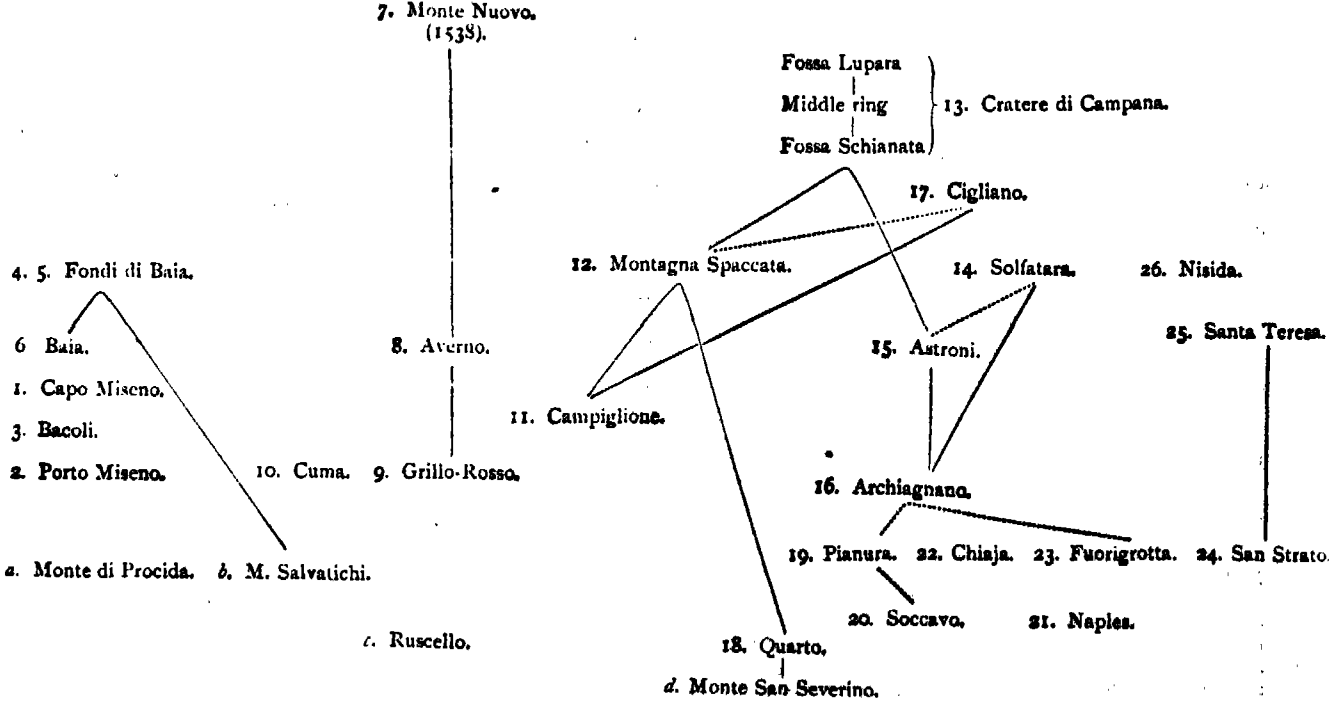
TABLE SHOWING SUPPOSED CHRONOLOGICAL ORDER OF FORMATION OF VOLCANOES OF PHLEGRÆAN FIELDS.



In all these cases of partially destroyed crater walls, their shape on the whole agrees very well with that of the five perfect crater walls enumerated above, and with the generalised type of a volcanic cone composed of fragmentary materials. In fact, there seems little reason to doubt their origin as segments of volcanic crater walls.

Passing now from the hills which bear a more perfect resemblance to a typical crater wall to those in which the resemblance is less perfect, I have been led to adopt the following criteria as indications: firstly, of whether a hill can be regarded as a segment of a volcanic crater wall or not; and, secondly, of the position of the volcanic crater.

(1) If a hill is convex towards one side and concave towards the other, it is assumed that the crater which it formerly surrounded was situated on the concave side; and the radius of the crater at any level is indicated by the radius of the arc formed by the horizontal projection of the horizontal curve of the crater slope at the same level.

(2) A further indication of position is afforded by the fact that in almost every case the natural crater slope is much steeper than the corresponding cone slope.

(3) If arc-shaped hills be so situated that a curve approaching a circle can be drawn so as to pass along all their ridges, it is an indication that the hills are parts of one and the same crater wall.

(4) In the Phlegræan Fields there is nothing more common than to find volcanic cones denuded on the side facing the sea. It is, therefore, probable that the last vestiges of a volcanic crater ring will be on the land side.

Examined with especial regard to these points, the hills of Baia, Monte Grillo and Monte Rosso, Cuma, Montagna Spaccata, and many others admit of interpretation as segments of volcanic crater walls. Lastly, there are some hills which may possibly be remnants of volcanic cones; but if they are, they are so worn and denuded that I have not been able to assign any position on satisfactory evidence to the vent from which they have been erupted.

The hills of the Phlegræan Fields which are considered to have once formed part of the walls of volcanic craters whose position is sufficiently well-indicated by the criteria enumerated above, are shown in the accompanying map. The map was constructed by drawing lines along the highest ridges of the hills enclosing undoubted volcanic craters, and then along those of less certain origin. The lines were then thickened according to a definite scale in which the breadth of line was made proportional to the height of the hill above sea-level. The highest hills in the north-east are over 1500 feet above sea-level, and are represented by the broadest lines.

One of the most striking features brought out in this map is that several of the crater-ring walls end abruptly in the circumference of others. Where this is the case it is assumed that the crater wall ending in the other is the product of a more ancient eruption. If this assumption prove to be correct, we have a very easily observable indication of the relative ages of the intersecting hills. Confirmatory evidence is often supplied by the physiographical characters of the hill slopes themselves. The slopes of the older crater walls seem to be, as a rule, less steep, and to exhibit the weather-worn scars of erosion and denudation to greater perfection than the steeper gradients of the younger crater slopes.

In the table given on p. 584 are set forth the volcanic structures so as to indicate their chronological relationships, so far as I have been able to make them out. The only crater of known age is Monte Nuovo: the most

salient features of its eruption were recorded by an eye-witness in the sixteenth century. The others probably date from prehistoric times; otherwise, such a marvel as an extensive eruption could not have escaped mention by some Greek or Roman author. In the table, the younger volcanic structures are arranged above those which are considered to be older, and lines connect those between which it is thought that some evidence of relative age can be detected.

In my recent paper I have shown that almost all the hills of the Phlegræan Fields are either the entire walls of volcanic craters or of portions of walls of volcanic craters which have been to a greater or less extent washed away by the action of rain or the sea, or have been partially destroyed or buried by more recent volcanic eruptions. Secondly, these volcanic craters are distributed over a crescentic area round the Bay of Pozzuoli; the more recent ones are situated closer to the shore of the bay than the older ones, indicating a gradual march of volcanic vents along lines radiating towards the centre of that bay. In other words, the general effect of volcanic activity has been the accumulation of new land around the bay of Pozzuoli. Inasmuch as water seems to be a necessity for a volcanic eruption, this progression of the volcanoes seawards may stand in some relation to the channels by which water has obtained access to the fires below.

Thirdly, wherever crater rings of a larger and smaller diameter overlap, we never find a larger ring superimposed on a smaller one. The smaller ring is always superimposed on the larger. The conclusion to be drawn is, that the volcanic activity of the region has been decreasing in intensity. The same proposition is proved for a single locality by the Campana series of craters.

As it is impossible to make all the above-mentioned points clear without a suitable map, I would draw the attention of the interested reader to the surveys of the region published by the Istituto Geografico Militare, and to the contoured map published in the *Geographical Journal* for October 1897.

R. T. GÜNTHER.

THE PRESENT APPEARANCE OF JUPITER.

IT may be interesting, now that the planet Jupiter is very favourably situated, to call attention to a few of the more conspicuous features which diversify its surface. Many of these objects will be sure to have come under the repeated observation of all those observers who have been habitually examining the planet in their telescopes.

It is fortunate that at the present time there are a large number of conspicuous markings on the planet. These are situated in different latitudes, and will allow some excellent redeterminations to be made of the velocities of the various longitudinal currents.

There are a great many dark and bright spots visible near the equator, on the north side of the southern equatorial belt. Some of these at the date of writing (April 18) are placed in the following longitudes, which are computed on the basis of System I. (daily rate 877°·90 = 9h. 50m. 30s.) in Mr. Crommelin's ephemerides in *Monthly Notices* for January 1898.

	Bright spots.	Dark spots.
	°	°
Long.	80	71
,,	146	94
,,	209	116
,,	238	127
,,	270	155
,,	349	216
		279
		319
		355

These markings are moving at approximately the same rate as the zero meridian System I.; but I find that in several cases there is a disposition of the spots to decrease in longitude; hence I believe that their rotation periods will prove to be slightly less than 9h. 50m. 30s. The bright spots exhibit great variations in their appearance, and some irregularities of motion. A spot which is conspicuously brilliant on one night may, a few evenings later, have declined so much that it can scarcely be discerned.

The great red spot is still visible, and its present longitude is about 24°, so that it follows the zero meridian of System II. in the ephemerides by about forty minutes. The spot has the aspect of a faint dusky ellipse with a light interior, and it is connected on its south side with a grey belt. The recent motion of the spot corresponds with a period of 9h. 55m. 41·5s., and it may be expected to drop further behind its computed place unless an acceleration of motion should set in. Comparing an observation of the spot which I obtained on April 17, 1898, 12h. 5m., with one of the earliest by Mr. Dennett, of Southampton, on July 27, 1878, I find that 17,414 rotations were performed in the interim of 7203 days, and that the mean period of rotation was

9h. 55m. 39·4s.

This value is identical with that found by Prof. Hough from 14,505 rotations between 1879-96.

In July 1898 the spot will have been visible during twenty years, and under careful observation at each opposition of the planet. Whether this object is identical with other elliptical or reddish spots seen at various times in the same latitude by Dawes (1857), Huggins (1858-59), Gledhill (1869-70), Lord Rosse (1873), Copeland (1873), Russell (1876), and others, must remain an open question. It appears highly probable that the spot was the same as that observed by Russell in the summer of 1876, but there is an absence of connecting observations in 1877. And the identity of two or more markings cannot be absolutely proved by their longitudes when a fairly long interval has intervened between the observations, because the proper motions of the object are variable, and introduce great differences of longitude not always in the same direction. The retarded westerly drift of the red spot has caused it to lose more than 900 degrees of longitude relatively to its place in 1878, so that the spot has really been displaced to the extent of about two and a half circumferences of the planet.

From my own observations of the spot since 1880, I have obtained the following rotation periods for a certain interval during each apparition:—

Limiting observations.	Rotations.	Period. h. m. s.
1880 Sept. 27-1881 March 17	413	9 55 35·6
1881 July 8-1882 March 30	640	9 55 38·2
1882 July 29-1883 May 4	674	9 55 39·1
1883 Aug. 23-1884 June 12	710	9 55 39·1
1884 Sept. 21-1885 July 8	700	9 55 39·2
1885 Oct. 24-1886 July 24	659	9 55 41·1
1886 Nov. 23-1887 Aug. 2	609	9 55 40·5
1888 Feb. 12-1888 Aug. 22	462	9 55 40·2
1889 May 28-1889 Nov. 26	439	9 55 40·0
1890 May 22-1890 Nov. 25	451	9 55 40·2
1891 Aug. 7-1892 Feb. 2	432	9 55 42·2
1892 Aug. 15-1893 March 8	495	9 55 42·3
1893 Aug. 9-1894 March 24	548	9 55 41·2
1894 Nov. 25-1895 May 10	401	9 55 41·2
1895 Aug. 24-1896 Feb. 22	439	9 55 41·3
1896 Sept. 27-1897 April 25	514	9 55 40·8

The red spot has been falling behind the zero meridian during the last six or seven years, but at a very slow rate, the mean annual retardation being only about six minutes.

There are a number of dark, elongated spots or short belts placed in various regions of the planet. They are conspicuous objects on nights when the seeing is good, and the times of their passages across the planet's central meridian are easily secured. The following are the longitudes of a few of these formations as computed from System II. of the ephemerides :—

		Long.
1. Dark elongated spot in	Lat. + 15° ...	120°
2. ,, ,,	Lat. − 35 ...	150
3. ,, ,,	Lat. + 15 ...	254
4. ,, ,,	Lat. + 33	268
5. ,, ,,	Lat. + 39 ...	282
6. ,, ,,	Lat. + 15 ...	298

Nos. 1, 3 and 6 are placed in the bright tropical zone, and immediately outlying the northern edge of the north equatorial belt. They are moving somewhat faster than the red spot, as their longitude appears to be decreasing at the rate of about 10° per month. Nos. 4 and 5 in the north temperate zone are moving at approximately the same velocity as the red spot.

There are some well-defined irregularities in the north side of the northern equatorial belt, which exhibits both white and dark spots. Their motion is evidently controlled by a rapid current similarly to that of the white and dark equatorial spots, but not, perhaps, quite so extreme.

Bright spots appear in the zone south of the red spot, and several of these are being attentively followed with the object of determining their periods.

On the whole the planet's appearance is now singularly replete with detail, and will compare favourably with that exhibited at any previous opposition. The great red spot has, it is true, long since lost the intense brick-red colour it displayed in the years 1878-81 ; nor have we now the exceedingly brilliant white equatorial spots of the period named. But appearances are now visible on the disc which were absent then, and among the most interesting of these are the elongated dark spots situated just outside the margin of the north equatorial belt.

Though past observation has fully demonstrated the proper motions of the different markings and the decreasing velocity of several of them, it is highly important that the rate of the various currents should be redetermined every year. The character and number of the spots found in them should also be recorded, and measures made to determine the latitudes of the belts. Pursued through a long series of years, such data might ultimately give us the proof of periodical variations in the character and number of the spots, and possibly also in their rates of motion. W. F. Denning.

THE LONDON UNIVERSITY BILL.

THE friends of education and many friends of the Government are disappointed at the postponement of the second reading of this Bill in the House of Commons. The cynics are saying that aristocratic Government and University representation are either jointly or severally responsible for this recurrent paralysis in the treatment of a question of the greatest importance to the greatest city of the world.

Nature is not a political organ, and these points need not therefore occupy us ; we can only express regret that the way in which all matters connected with science and education are handled in this country is so vastly different from that meted out to them in France or Germany. The *Times* writes as follows :

> It is no longer denied in any quarter that the absence of a teaching University in the capital of the British Empire and the greatest city in the world is an anomaly and almost a scandal. The alternative which commends itself to Mr. Moulton and the anti-reform party is that a new teaching University should be set up alongside of the present examining University, but this scheme has been rejected by the vast majority of intelligent men who have taken even the slightest pains to look into the subject. What the Government desire—in accordance, we believe, with the immense preponderance of authority on this question—is to connect a teaching University, under which degrees will be given as the hall-mark of a systematic intellectual training, with the existing system of examination pure and simple. The latter, it is pointed out, is left entirely untouched, though there is a strong and growing conviction that it never can be, even in part, a true development of the highest education, but must tend, more and more, to pass under the dominion of the crammer. But the preservation of the existing method of giving degrees makes it imperative, if the teaching work of the University is to be a reality and not a sham, that there should be a double system of examinations, the one for "internal" and the other for "external" students. The Bill provides, necessarily and inevitably, for this distinction, but the most careful securities are adopted that no unfair advantage shall be given to the former class, and, especially, that the examination of students by the teachers who have trained them shall be supplemented and checked by the admission of an independent element. It would seem to be forgotten that the medical degrees of the London University, which undoubtedly stand highest in public estimation and of which the standard is rigorously high, are granted on the reports of examiners many of whom are teachers in the medical schools. The cry for identity of examinational tests is irrelevant and inconsistent. It is, as Dr. Allchin urges, "an attempt to subordinate the examinations to the requirements of those who have neither been trained nor educated in the fullest sense of the word." This is the very essence of the bondage from which for many years past the higher education in London has been struggling, under the guidance of such men as Huxley, to escape, and from which deliverance is now in sight, if Ministers will only have the courage of their opinions and be true to their pledges.

Whether the paralysis comes from want of knowledge or want of courage, it is very clear that there is at the present a great gap in our administrative machinery, and one which a Scientific and Educational Committee of the Privy Council might easily fill if the right men were appointed to it.

NOTES.

The death is announced of Prof. Aimé Girard, member of the Section of Rural Economy of the Paris Academy of Sciences. Referring to the deceased investigator at the meeting of the Academy on April 12, M. Th. Schlœsing remarked : M. Aimé Girard was the highest authority on chemical and agricultural industries in the Academy. After some valuable scientific work he was nominated professor of industrial chemistry at the Conservatoire des Arts et Métiers, in succession to Payen. His teaching revealed the dominating object of his efforts. Affable and cheerful, loyal and entirely disinterested, he possessed all the attributes required to gain the confidence of manufacturers. The producers whose places he visited, in France and in other countries, became and remained his friends ; they gave to him a large amount of information which he used to enrich his attractive lectures, and in return M. Girard offered them advice suggested by his experience and his own investigations. In a few years his masterly researches on vegetable fibres, wheat, farinas, sugars and woods had made him the first authority upon these matters, and he was frequently consulted by the Government on subjects concerning the great industries of paper, alcohol, sugar, flour, and bakery. The study of these products led to inquiries as to crops. In this new direction M. Girard rendered valuable services, and, after his researches on the cultivation of sugar-beet and the improvement of the potato, he obtained among agriculturists the same position and the same sympathies which he enjoyed in the industrial world. Though weakened in recent years by illness, and saddened by repeated troubles, he nevertheless continued his work. He died while occupied in applying to wheat of various origins the new methods of analysis which were the subject of a recent communication to the Academy. The vacancy which his death has caused enables us to estimate the high place which he occupied in scientific societies and in the committees in which he took part.

WE learn from the *Electrician* that a banquet to M. Z. Gramme, to celebrate his receiving the decoration of Commander of the Ordre Léopold, was lately held at the Hôtel Métropole, Brussels. The Senator, M. Montefiore-Lévi, presided, and among the guests, who numbered 130, were Prince Roland Bonaparte, the Minister M. Nyssens, representing the Belgian Government, the Burgomaster and Aldermen of Brussels, M. Mascart (president of the Organisation Committee), M. A. d'Arsonval (president of the Société Internationale des Electriciens), and M. Hippolyte Fontaine, manager of the Gramme Company. M. Mascart, in an eloquent speech, traced the career of M. Gramme, from his commencement as a simple workman in the tiny Belgian village of Jehay-Bodégnée down to the present day, and presented the great Belgian electrician, in the name of the electricians of the whole world, with a fine gold medal engraved by Chaplain. After the banquet the guests were received by the Town Council in the Hôtel de Ville. Profs. Ayrton and Silvanus Thompson, who had been appointed delegates by the Institution of Electrical Engineers, were unable to reach Brussels on account of a storm, and the illuminated address of congratulation, of which they were to have been the bearers, had to be sent by post. Numerous congratulatory telegrams were received, including one from Lord Kelvin and one from Mr. W. H. Preece.

THE ninth international Congress of hygiene and demography was opened at Madrid on April 10. About two thousand members attended the Congress, but less than fifty English delegates were present. The opening ceremony took place in the National Library, under the presidency of the Minister of the Interior, who was supported on the right by the Governor of Madrid, the acting President of the Congress, Dr. Julian Calleja, and by the Secretary-General of the Congress, Dr. Amalio Gimeno; on the left by Prof. Brouardel (Dean of the Paris Faculty of Medicine) and the Mayor of Madrid. Dr. Calleja delivered the inaugural address, and in a few words of greeting extended a warm welcome to the members of the Congress, wisely reminding the audience that the science of public health was confined to no nation in particular and to no one science specially. Dr. Brouardel spoke on behalf of the Permanent International Committee, and he was followed by delegates from the nations represented at the Congress, after which the Minister of the Interior pronounced the Congress open. In the evening a gala performance was given in honour of the members of the Congress at the Spanish Theatre. A reception was held at the Athenæum Literary Club on the evening of Monday, April 11, and on Friday, April 15, there was a reception of the members of the Congress at the house of the Prime Minister, while on Saturday certain delegates had the honour of presentation at Court. The scientific work of the Congress was carried on in the various sections during the whole of last week, and a large number of papers of importance to the science of public health were read.

THE fifth centenary of Paulo Toscanelli and Amerigo Vespucci is being held with much gaiety at Florence. The festivities will continue until the end of this month, and the programme comprises a geographical congress and the inauguration of several monuments.

ABOUT 10.15 p.m. on Tuesday, April 5, a meteor of exceptional size and brilliancy was observed at Ealing slowly traversing the sky in an easterly direction. After a few seconds the meteor burst, and then shot forward with increasing velocity, and disappeared after being visible about ten seconds.

A LECTURE upon "The Progress of Optics during the Present Century" will be delivered at the Mansion House this evening, by Dr. G. Lindsay Johnson, under the auspices of the Worshipful Company of Spectacle Makers. The Lord Mayor, and subsequently the Astronomer Royal, will preside at the lecture.

THE ninth annual meeting of the Museums Association will be held at Sheffield in the first week of July. The Lord Mayor and Corporation of Sheffield offer a cordial welcome to all members of the Association, and are very desirous of making the meeting in every respect successful. All the business will be carried on in the Town Hall, the use of which has been granted to the Association. The President-elect is Alderman W. H. Brittain, and the Secretary is Mr. E. Howarth, Public Museum, Sheffield, to which address communications from members who propose to read papers should be sent.

AT the annual meeting of the Iron and Steel Institute, to be held on Thursday and Friday, May 5 and 6, under the presidency of Mr. Edward P. Martin, the Bessemer gold medal for 1898 will be presented to Mr. Richard Price-Williams in recognition of the active part he took in the early days of the use of steel on railways. Among the subjects of papers that are expected to be read and discussed are: The iron industry of the Urals, by Prof. H. Bauerman; the solution theory of iron, by the Baron Hanns Jüptner von Jonstorff; brittleness in soft steel, by Mr. C. H. Ridsdale; allotropic iron and carbon, by Mr. E. H. Saniter; the crystalline structure of iron, by Mr. J. E. Stead.

THE third annual Congress of the South-eastern Union of Scientific Societies will be held in the Town Hall, Croydon, on June 2-4. On Thursday evening, June 2, the President-elect, Prof. G. S. Boulger, will deliver the annual address. Among the papers to be read on the following day are—entomology as a scientific pursuit, by Mr. J. W. Tutt; the place of geology in education, by Prof. Logan Lobley; the nature of the soil in connection with the distributions of plants and animals, by Dr. H. Franklin Parsons; natural gas in Sussex, by Mr. C. Dawson. On Saturday, June 4, a discussion will take place on ideals for natural history societies, and how to attain them; and Mr. E. M. Holmes will read a paper on botanical work still wanting workers. A museum arranged by the local committee, illustrating the natural history of the neighbourhood and other subjects, will be open during the Congress.

THE *Times* correspondent at Athens writes, under date April 18:—The French School of Archæology was to-day the scene of a brilliant assembly. The King, who was accompanied by the Crown Prince and Princes George and Nicholas, arrived at eleven o'clock, and tendered his congratulations to M. Homolle, director of the School, on the occasion of its jubilee. M. Zaimis (the Prime Minister), M. Romas (President of the Chamber), M. Delyanni, M. Ralli, and all the principal members of Athenian society were present, together with a great concourse of foreign visitors. In the course of an interesting address, M. Homolle made the announcement that M. Syngros, the Greek millionaire, had decided to erect a museum at Delphi. Speeches were then delivered by M. Cavadias, in the name of the Greek Archæological Society, by Dr. Dörpfeld, on behalf of the foreign schools in Athens, and by M. Collignon, as representing various French scientific institutions. Count d'Ormesson, the French Minister in Athens, also delivered an address.

BY establishing a National Zoological Park, having for its chief object the collection and preservation of American animals likely to become extinct, the Smithsonian Institution has been the means of developing an intelligent interest in such collections in the United States, and has stimulated other enterprises of a similar character. Among similar zoological preserves, which have been projected and established in the United States since the establishment of the National Zoological Park, are the following:—The Blue Mountain Forest Park, established by the late Mr. Austin Corbin, is a large tract of forest and abandoned farm land, situated in the western part of New Hampshire, comprising an enclosed area of 26,000 acres. Within this enclosure are kept about 4000 wild animals, including 74 bison, 200 moose, 1500 elk, 1700 deer of different species, and 150 wild boars. These animals are rapidly multiplying, and, with the exception of the bison, which are sheltered and fed during the winter, live in perfect freedom. In the Adirondack region of New York a game preserve of 9000 acres has been stocked with elk, Virginia deer, mule deer, rabbits, pheasants, &c., and Mr. W. C. Whitney has established a preserve of 1000 acres in the Berkshire hills, near Lenox, Mass., where he maintains not only the species of animals above mentioned, but also bison and antelope. Other preserves are Ne-ha-sa-ne Park, in the Adirondacks, 8000 acres; Tranquillity Park, near Allamuchy, N.J., 4000 acres; the Alling preserve, near Tacoma, Wash., 5000 acres; North Lodge, near St. Paul, Minn., 400 acres, and Furlough Lodge, in the Catskills, New York, 600 acres. These are all fenced enclosures, well stocked with animals. At Pittsburg, Pennsylvania, in one of the public parks, a number of buildings intended for the exhibition of animals are being constructed. These are already nearing completion, and will cost more than 200,000 dollars, exclusive of the animals they are to contain. A further collection of buildings and enclosures intended for American animals only is also projected for that city. Finally, the New York Zoological Society has obtained from the city of New York a grant of some 261 acres in the southern portion of Bronx Park, near that city, for the purpose of establishing there a zoological garden, which is to be free to the public for at least five days in each week. Plans are now being prepared for the development of a collection on the most generous and attractive scale. The bulletin issued by the Society states that it is expected that there will be at once spent 125,000 dollars for preparing the ground, and 250,000 dollars for buildings and enclosures.

THE colony of beavers in the National Zoological Park, Washington, have now made themselves completely at home. The animals have constructed three large dams, one of which is at least 4 feet high. Each of these has been built wholly by the beavers themselves, either from trees felled by them within the enclosure or from branches furnished them for food. They cut this material into suitable lengths, which they drag to the water, float to the dam, and there combine with mud and twigs to form a compact structure. In connection with each dam they have built houses, together with several smaller burrows in the bank. The entrance to the houses is always under water, and can only be reached by diving. The animals have become quite accustomed to the presence of man, and it is believed that under proper restrictions the public may be allowed to see them at work.

DR. A. SLABY, professor of electro-mechanics, and heat-mechanics in the Technical High School at Charlottenburg, contributes to the *Century Magazine* (April) an illustrated article upon telegraphy by electric waves—*stromtelegraphie* or "telegraphy by circuit" he terms it. Prof. Slaby describes how he succeeded in establishing communication between Schöneberg, near Berlin, and Rangsdorf, at a distance of twenty-one kilometres. The Emperor of Germany ordered the balloon department of the army to assist in the experiments, and balloons were anchored at the two places chosen for the transmitting and receiving stations. At both stations thin copper wire was fastened to the baskets of the balloons, reaching two hundred and fifty metres to the apparatus. Connection with the earth was made by means of swords stuck in the ground. The first telegram received under these conditions is reproduced in the article, and the clearness of the Morse characters upon it is most remarkable. The distinctness of the dots and dashes seems all the more noteworthy because of the highly electrical condition of the atmosphere on the day of the experiments. The results demonstrated the possibility of using captive balloons on the high sea for purposes of communication by ethereal telegraphy. In place of balloons, kites of the modern form can be used; for Prof. Slaby says a few experiments have convinced him that they are perfectly adapted to carrying the thin wires required to connect with the apparatus. In connection with Prof. Slaby's observations, it is noteworthy that, during the past few months successful experiments on electrical communication without intervening wires have been made at places on the South Coast, under the direction of Signor Marconi. Regular communication has been maintained between Bournemouth and Alum Bay—the distance between the two stations being about 14½ miles. Signals have also been exchanged between stations 18 miles apart, and arrangements are being made to test the capabilities of the instruments to receive at Cherbourg signals transmitted at Bournemouth—the intervening distance being about 60 miles.

THE concluding part of the 26th *Ergänzungsband* of *Petermann's Mittheilungen* contains a very comprehensive account of the distribution of rainfall over the solid portions of the globe, by Dr. A. Supan. The first rain-chart of the world was published by Prof. E. Loomis in 1882, in the *American Journal of Science*. During the last fifteen years the number of rainfall stations has greatly increased, and the quality of the observations has, generally speaking, much improved. Still the distribution is far from satisfactory, as more than half of the observations emanate from Europe, and even there large tracts are badly represented. The construction of a rain-chart always presents great difficulties, because the distribution of rainfall depends so greatly upon local conditions, upon the exposure of the gauges, and the accurate measurement of snow. And to be strictly comparable the periods ought to be the same. But in a comprehensive work, such as that now in question, the author has no choice but to select the best available materials, and this Dr. Supan has done, and gives full particulars as to the sources from which the information is obtained. In addition to tables giving the monthly and yearly values, the author gives a full discussion of the rainfall of various districts, and the charts show very clearly both the mean annual amounts and the seasonal distribution. The work forms a valuable contribution to our knowledge of the subject.

REFERRING to the report from Vienna that Dr. Schiff has successfully treated cases of lupus vulgaris by means of Röntgen rays, the *British Medical Journal* remarks that his process is to set up an independent inflammation in the lupoid area by exposing the part to a very intense radiation. So far, investigations into the germicidal effects of Röntgen rays have gone to show that their activity in this respect is not greater than that of ordinary light. But Dr. Schiff's result is not a germicidal one, and it is known that inflammation, and even necrosis, may result from exposure in certain cases, although the determining factor which leads to injury in some cases but not in others under apparently similar conditions is unknown. It is not, however, altogether improbable that Dr. Schiff's results may be due to a direct germicidal action of Röntgen rays on the tubercle bacillus. Light is deleterious to this organism, and Dr. Finsen, of Copenhagen, has reported cases of cure in lupus by protracted exposure to concentrated light, so arranged that the ultra-violet rays predominated.

WE have received the first part (for 1896–97) of the *Transactions* of the British Mycological Society. Descriptions are given of several new Fungi, or of species new to Britain.

THE *Botanisches Centralblatt* states that Dr. C. Marchesetti has undertaken a botanical expedition to Upper Egypt and Palestine; and Dr. M. Pedersen (of Copenhagen), an investigation of the vegetation of Disco Island, Greenland.

AT the venerable age of ninety, Prof. R. A. Philippi resigns the directorship of the National Museum at Santiago, Chile, which he has held for forty-three years. He is succeeded by his son.

AS "Circular No. 13," the United States Department of Agriculture (Division of Botany) publishes a description, with excellent drawings, of the edible and poisonous Fungi natives of the States, by Mr. Frederick V. Colville.

PROF. D. P. PENHALLOW reprints from the *Transactions* of the Royal Society of Canada a useful review of Canadian botany from 1800 to 1895, being a paper read before the Botanical Section at the last meeting of the British Association.

THE *American Naturalist* for February gives a full account of the first annual meeting of the Society for Plant Morphology and Physiology, held at Ithaca, N.Y., on December 28 and 29, 1897, at which many important and interesting botanical papers were read.

THE *Botanical Gazette* for March gives a list of the persons officially designated by the Government as botanists or mycologists in the United States, fifty in number. These are situated at fifty-one State experiment stations. Every State in the Union, with the exception of ten, has its State botanist, New York and Connecticut having two each.

THE firm of J. B. Baillière et fils, of Paris, is publishing a "Bibliographie Botanique," to appear in five monthly parts of 32 pp., each of two columns. The first fascicle, comprising the letters A to C, will appear shortly. The titles of about 10,000 volumes and pamphlets will be included in the work; the date of publication, number of pages, and some account of the contents will, in each case, be included.

UNDER the title, *Die Metamorphose der Pflanzen, im Lichte palæontologischer Thatsachen*, the well-known palæontologist, Dr. Potonié adduces arguments, derived from the geological history of plants, in favour of the view that all the higher forms of vegetable life have been derived, by metamorphosis, from the forking of an archaic thalloid structure.

THE *Biologisches Centralblatt* continues to publish a succession of interesting papers in both branches of Biology. The phenomena of impregnation in the Rhizopods, non-sexual propagation in Phanerogams, the relationship between the arctic and the antarctic plankton, spermatogenesis in *Paludina vivipara*, the relationships between Phanerogams and Cryptogams, are among the subjects discussed in the most recent numbers.

WE learn from the *Journal of Botany* that a new British flora is in preparation by the Rev. E. F. Linton, who will take the *London Catalogue* for the basis of his work. A large number of "forms," and not a few distinct species, have been added to our flora since the publication of the last edition of the existing manuals. The publication is also announced of a flora of Cheshire by the late Lord de Tabley, which will be edited by Mr. Spencer Moore. The flora of Kent, by Mr. F. J. Hanbury and the Rev. E. S. Marshall, is nearly ready for the press.

Petermann's Mittheilungen contains a new geological map of Java and Madura, by Dr. R. D. M. Verbeek, which is a considerable advance on that published by Junghuhn in 1855. A short paper discusses the relation of the topography of the islands to their geological structure.

DR. MAX ECKERT, of Leipzig, contributes a paper to *Petermann's Mittheilungen* on the Karren and Schratten districts of the German Alps. Various forms of primary and secondary Karren are recognised; the most typical form occurring in pure chalk at levels where weathering is greatest—*i.e.* between 1600 and 2300 metres.

IN a paper published in the *Zeitschrift für praktische Geologie*, Prof. Dr. Rudolf Zuber, of the University of Lauberg, discusses modern theories of the formation of petroleum. The author believes that the hypotheses at present in the field are either too purely chemical or too purely geological, and he criticises a number of them from this point of view, without, however, advancing anything definitely new to take their place.

WE have received a reprint, from the *American Antiquarian*, of a paper on the geography of the Tsimshian Indians, by Mr. G. A. Dorsey. The Tsimshian Indians form one of the most important stocks of the North-west; they inhabit villages on the Nass and Skeena rivers of British Columbia, and are distinct in language from the neighbouring tribes. Mr. Dorsey's paper chiefly consists of a list of the villages, and notes as to name, position, &c., of each.

THE instruments devised for recording the occurrence of an earthquake, or analysing its motion are very numerous, and are described in many scientific journals. Dr. R. Ehlert has, therefore, rendered a great service by collecting and classifying in one memoir (Gerland's *Beiträge zur Geophysik*, vol. iii.) the accounts of all the more important seismographs and seismoscopes that have so far been constructed.

THE latest addition (No. 1084) to the Smithsonian Miscellaneous Collections is a "Bibliography (1748–1896) of the Metals of the Platinum Group"—platinum, palladium, iridium, rhodium, osmium, ruthenium—by Prof. J. L. Howe. The publication of this volume was recommended by the Committee of the American Association for the Advancement of Science having charge of indexing chemical literature. All papers upon metals of the platinum group found in scientific literature to the close of 1896 are given in the order of the date of appearance, and are also indexed according to subjects and authors. It is thus easy to determine what papers have been published upon the physical and chemical characteristics and properties of any members of the platinum group of metals. The volume will therefore be of the highest value to many scientific investigators; and by publishing it the Smithsonian Institution has increased the obligations which men of science owe to the Institution for making works of this character available.

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (*Macacus cynomolgus*, ♂) from India, presented by Mr. H. Times; a Silver-backed Fox (*Canis chama*), a Suricate (*Suricata tetradactyla*) from South Africa, presented by Mr. W. Champion; a Grey-breasted Parrakeet (*Myopsittacus monachus*) from Monte Video, presented by Mrs. Evelyn Heathcote; a Gold Pheasant (*Thaumalea picta*, ♂) from China, presented by Mrs. Abbot Robinson; a Long-necked Chelodine (*Chelodina longicollis*) from Australia, presented by Mr. R. Kirkwood; an Isabelline Bear (*Ursus isabellinus*) from India, deposited; a Red-vented Cockatoo (*Cacatua hæmaturopygia*) from the Philippine Islands, two Toco Toucans (*Ramphastos toco*) from Guiana, a Lapwing (*Vanellus cristatus*), two Knots (*Tringa canutus*) from Lincolnshire, purchased; a Gayal (*Bibos frontalis*, ♀), a Mouflon (*Ovis musimon*, ♂), a Hog Deer (*Cervus porcinus*, ♀), born in the Gardens.

OUR ASTRONOMICAL COLUMN.

Comet Perrine.—The following is a continuation of the ephemeris of Comet Perrine for the ensuing week, from Prof. H. Kreutz's computation:—

1898.		R.A. h.	m.	s.		Decl. °	′		Br.
April 22	...	23	48	19	...	+46	15·0	...	0·64

25	...	0	4	19	...	47	57·1		
26	...		9	42	...	48	28·7	...	0·58
27	...		15	6	...	48	59·0		
28	...	0	20	32	...	+49	28·1		

The Aurora Spectrum.—Prof. E. C. Pickering tells us in a *Circular* (No. 28) of the Harvard College Observatory that the attempts made at photographing the spectrum of the aurora have proved successful, Mr. Edward S. King having obtained two plates, one on April 1, 1897, and the other this year on March 15. On the first of these photographs four bright lines were visible after an exposure of 147 minutes, but uncertainty existed as to the wave-lengths of these lines. In the more recent negative two bright lines were obtained after an exposure of 141 minutes. The brightest of these extends from 3892 to 3925, the wave-length of the second being 4285. Assuming that these two lines were photographed in 1897, the wave-lengths of the four lines then obtained would be 3862, 3922, 4288, 4694.

As regards the first two lines, 3862 and 3922, nothing as yet can be said, as visual observations of the aurora have not extended so far. The line 4288 seems probably to be the same as observed in previous auroræ by Lemström, Wijkander and Oettingen, the wave-lengths given by them being 426, 428 and 424 respectively. The last of the four lines at 469 is a well-observed aurora line, having been seen no less than nine times by observers; its probable origin is the hot carbon band, which extends from 467–474.

Prof. Pickering mentions that the spectroscope employed to obtain these photographs was not specially designed for the purpose, but a new instrument is in course of construction with which it is hoped better results will be obtained.

The Movement of Solar Faculæ.—By a minute study of the magnificent series of observations on sun-spots, made by Carrington and Spörer, the difference between the times of rotation of the spots in different latitudes has been determined with great accuracy. Thus a strict relation was found to exist between the angular velocity of any spot and its latitude, the former decreasing as the latter increased. Dunér further showed that exactly a similar law existed in the case of the general surface of the sun, but with this exception, that the velocities of each latitude for latitude did not agree. An interesting inquiry was then to investigate the behaviour of the faculæ, which recent photographic methods have shown are so numerous over the solar disc. Faculæ, as many observers of the sun know, are not such stable phenomena as spots; nevertheless Wilsing, after a laborious investigation, came to the conclusion that they were imbued with a velocity that was constant for all latitudes, and equal to a movement of 14°·27 in 24 hours. Belopolsky, at a later date, adopted a different method of investigation, and was led to draw the conclusion that faculæ obeyed the same law of the variation of the angular velocity of rotation as the spots. More recently Wolfer, after a method somewhat analogous to that employed by Wilsing, came to the same conclusion as that arrived at by Belopolsky.

In consequence of the high importance that would be attached to a definite result of so interesting a problem, Dr. W. Stratonoff has undertaken a very complete investigation of the whole subject, using as his data the fine photographs that have been obtained in the last few years (*Mémoires de l'Académie Impériale des Sciences de St. Pétersbourg. Classe Physico-Mathématique*, vol. v. No. 11). Out of a total number of 400 plates, for the years 1891–1894, he used 234 for this research, as will be seen from the following list, showing by whom they were taken:—

1891	...	60	... Belopolsky.
1892	...	57	... ,,
1893	...	76	... ,, and Stratonoff.
1894	...	41	... Stratonoff, Orbinsky and Evdokimoff.
Total		234	

We cannot enter at length into the details of the method M. Stratonoff has employed in this long investigation, but must confine ourselves simply to the results obtained. The measurements of the heliographic latitudes and longitudes of each of the 1062 faculæ employed are given in the communication in one table, while a second is confined to the heliographic latitude of each facula with its angular velocity of rotation. The sum total of the research is that Wilsing's result is not corroborated, for it is found that the faculæ in different latitudes do not move with a constant velocity; in fact, the variation of the angular velocity of rotation must be represented by a more complicated law than that in use for the spots. For latitudes 0°–8° the angular velocity of the faculæ remains nearly constant; from 9°–16° it decreases rather rapidly to the extent of nearly 0°·4; for some range of latitude the velocity becomes again nearly constant, tending to increase rather than decrease. A rapidly slowing down of about 0°·5 takes place between latitudes 25° to 34°, and after that in higher latitudes a very gradual diminution in velocity is noticed more pronounced than was the case in the equatorial zone. Thus it will be seen that velocities of rotation at the highest and lowest latitudes differ by nearly a degree, the characters of this variation being the same for both hemispheres. Spots, it may be added, have the tendency to diminish the velocity of rotation of faculæ. As regards the movements of faculæ, spots, and the solar surface, the faculæ in all latitudes have the greatest velocity of rotation; then come the spots which move more slowly, and lastly the solar surface, which has the least movement of all. M. Stratonoff suggests that perhaps these facts owe their origin in their difference of heights above the envelope of the sun. The author concludes his interesting paper with a series of instructive curves which convey very clearly to the eye the results of the investigation.

YEAST AND ALCOHOLIC FERMENTATION.

Though the knowledge of the existence of alcoholic fermentation and the preparation of alcoholic liquids dates back to very remote antiquity, it is only within comparatively recent times that an accurate acquaintance with the actual nature of the process has been obtained. By the older writers many processes have been confused together under the name fermentation, though they have nothing in common but the evolution of gas which takes place as they go on. The true alcoholic fermentation, the formation of gas in the intestines of animals, and the effervescence which takes place when an acid is poured upon chalk, have all thus been grouped together as comparable phenomena. Of these different processes, however, that of alcoholic fermentation has been made most widely a subject of study, and from about the end of the seventeenth century definite views as to what it really consists of have been entertained by scientific men.

The correspondence between the alcoholic fermentation of the wort of beer, the must of wine and other saccharine liquids, and the disengagement of a gas under the influence of leaven in the manufacture of bread, had been noticed at a considerably earlier period. Very strange ideas were entertained as to the nature and action of the leaven. It was by some writers held to be of the same nature as that of the hypothetical philosopher's stone, and just as the latter was supposed to be able to transmute all metals by contact with them, so the leaven was considered to be able, in some occult way, to transform the dough into something resembling itself. One fact of importance comes out amidst all the mass of confusion, though its interpretation leaves much to be desired. This is the discovery that a very small quantity of leaven is capable of transforming an almost indefinite amount of the dough. The dough was, however, thought to be converted into leaven, and the capability established was distorted into a mark of identity with the philosopher's stone.

It was known, too, at an early date that besides an evolution of gas, alcoholic fermentation is always accompanied by the formation of a deposit in the fermenting liquid, which takes the form sometimes of a sediment, sometimes of a scum floating on the surface. By many writers considerable importance was attached to this deposit, and to it was attributed some special occult force capable of determining the changes which could be observed. These changes were held by some investigators to be chemical in nature, but still to be altogether different from ordinary chemical reactions. Valentin, who wrote towards the close of the sixteenth century, suggests that the deposited matter communicates to the liquid a kind of internal inflammation, and determines thereby a purification of it, separating its limpid from its turbid constituents. Valentin realised that alcohol makes its appearance in the fermenting liquid, but supposed that it was in some way pre-existent in the extract of the germinated barley grains, and became active and capable of distillation only after being liberated from impurities which accompanied it, and which masked its special properties.

Van Helmont, who wrote in 1648, though confusing fermentation with effervescence, like most writers of the time, yet distinguished that a special gas, which he called the "gas of wine," was produced during the former action, and pointed out that it was different from the spirit of the wine.

Attention was drawn to a distinction between effervescence and fermentation by de la Boë in 1659 and by Lemery in 1675. The first of these writers held the sounder view as to this difference, stating that in effervescence the chief reaction is one of combination, while in fermentation it is a question of decomposition. Lemery held, less accurately, that the chief difference between them was one of relative rapidity, fermentation being a slower and more complicated process. This theory of fermentation is stated by himself in the following words:—

"Pour expliquer cet effet, il faut savoir que le moust contient beaucoup de sel essential; ce sel comme volatil faisant effort dans la fermentation pour se détacher des parties huileuses par lesquelles il etait comme lié, il les pénètre, il les divise et il les écarte jusqu'a ce que par ses pointes subtiles et tranchantes, il les ait raréfiées en esprit; cet effort cause l'ébullition qui arrive au vin, et en même temps sa purification; car il en fait séparer et écarter les parties les plus grossières en forme d'écume, dont une portion s'attache et se pétrifie aux côtés du vase, et l'autre se précipite au fond, c'est ce qu'on appelle le tartre et la lie. L'esprit inflammable du vin n'est donc autre chose qu'une huile exaltée par des sels."

Apparently, the first ideas on the subject that may be regarded as at all clear, were advanced by Becher in 1682, and they mark an epoch in the development of our knowledge of it. This author ascertained the fundamental fact that only saccharine liquids are capable of undergoing alcoholic fermentation, and he showed that the alcohol does not exist as such in the original must of wine, but is formed during the operation of fermentation. Becher thought its formation to be due to a kind of combustion, as he ascertained that access of air is needed to set up the phenomenon.

About the same time a theory of the nature of fermentation was advanced, which has much in common with the ideas maintained in later times by Liebig. This was due to Willis and to Stahl, both of whom entertained similar opinions on the subject. It was that the ferment which they recognised as the factor that started the operation is a body possessing a peculiar internal movement or vibration, and that it transmits this vibration to the fermenting material. Of course in the condition of chemical science at the time, there was no satisfactory statement possible as to the nature of the changes caused by such vibration, but Stahl suggested that various decompositions and recombinations resulted therefrom.

The next marked advance in our knowledge must be associated with the name of Lavoisier a century or more later. Up to his time no quantitative researches into the subject had been carried out. The bodies capable of fermentation had been ascertained up to a certain point; besides the alcoholic, the acetic fermentation had been discovered, and a general analogy had been established between fermentation and putrefaction. The products of these fermentations had been ascertained to be carbonic dioxide, alcohol, and acetic acid. Very little acquaintance had been made with the ferment, which was shortly to be recognised as a definite vegetable organism.

While Becher first pointed out the necessity for the presence of sugar in the fermenting liquid, Lavoisier studied quantitatively the relations of the sugar to the derivatives of it formed during the fermentation, and came to the conclusion that the operation consists of a separation of the sugar into two parts, one of which becomes oxygenated to form carbonic dioxide, while the other is converted into alcohol. He says that if it were possible to recombine these two substances, alcohol and carbonic dioxide, sugar would again be formed.

It is apparent that though Lavoisier's methods of analysis were imperfect, and his figures inaccurate in consequence, yet his general conclusions were sound. Towards the year 1815 analyses by Gay-Lussac, Thénard, and de Saussure fixed definitely the composition of sugar and alcohol. These more accurate analyses confirmed Lavoisier's position, but revealed a discrepancy which for a long time remained unexplained. Computation of the composition of sugar based upon the CO_2 and alcohol formed during its fermentation pointed to its having the formula $C_6H_{12}O_6$ (taking the modern values of the atomic weights), the decomposition being capable of expression by the equation $C_6H_{12}O_6 = 2C_2H_6O + 2CO_2$. The analysis made by Gay-Lussac and Thénard of cane-sugar itself demanded the formula $C_{12}H_{22}O_{11}$. These authors were unable to account for the discrepancy which remained unexplained till Dubrunfaut in 1832 observed that before cane-sugar could ferment, it became transformed into another form of sugar which is non-crystallisable. Dumas and Boullay in 1828 tried to reconcile the discrepancy by assuming that the fermentation is accompanied by the absorption of water. We have in the work of these three investigators the substance of what we now know to be true, that the fermentation of cane-sugar involves two processes, the hydrolysis of the cane-sugar with the formation of hexoses, and the decomposition of these with the formation of alcohol and carbonic dioxide.

During the progress of these investigations into the chemistry of fermentation a certain study of the fermenting body was being carried on by various observers. As long ago as 1680 the yeast of beer was examined microscopically by Leuwenhoek, who stated that it was composed of little ovoid or spherical globules, but was not able to determine their nature. Subsequent writers considered them to be of animal origin, but very little was definitely ascertained about them till the fourth decade of the present century, when Cagniard de Latour, repeating Leuwenhoek's experiments, saw that yeast is composed of a mass of organised globules capable of reproduction by budding, and appearing to belong to the vegetable kingdom. He concluded that very probably they disengaged the carbonic dioxide and fermented the liquid by some effect of their vegetation. Before de Latour and writers contemporary with him the yeast was generally considered to be of an animal rather than a vegetable nature, this view being promulgated especially by Fabroni, Desmazières, and Astier, the latter of whom held that it could only live at the expense of the sugar which it decomposed. Since the time of Meyen the true systematic position of yeast has been recognised.

The work of Astier and of C. de Latour laid the foundation for the more complete and satisfactory views of Pasteur, whose researches have thrown so much light upon the whole process of fermentation.

One of the most important discoveries that we owe to Pasteur is that alcoholic fermentation is accompanied by the coincident formation of glycerine and succinic acid, and that, therefore, the equation given above by no means represents all that is taking place in a fermenting liquid. Without committing himself to an equation to represent the whole decomposition, Pasteur determined by quantitative methods that about 4 per cent. of the sugar which disappears in the process of fermentation does not give rise to alcohol, but to glycerine and succinic acid. In addition to ordinary ethylic alcohol, also small quantities of higher alcohols, in varying quantities, are always or generally formed.

Pasteur's theory of fermentation is the natural outcome and the completion of the ideas of Astier and of C. de Latour. In his own words it may be stated: "Mon opinion la plus arrêtée sur la nature de la fermentation alcoolique est celle-ci: L'acte chimique de la fermentation est essentiellement un phénomène corrélatif d'un acte vital, commençant et s'arrêtant avec ce denier. Je pense qu'il n'y a jamais fermentation alcoolique sans qu'il y ait simultanément organisation, développement, multiplication de globules, ou vie continuée, poursuivie, des globules déjà formés."

This hypothesis, originally advanced by C. de Latour, did not, however, obtain acceptance at once. It was opposed strongly by Liebig, who put forward a view which is a modification of that advocated so long before by Willis and by Stahl. According to Liebig, the cause of fermentation is an internal molecular movement or vibration which a body in the course of its decomposition communicates to other matters whose elements are held together with very feeble affinity. Liebig says: "La levure de bière, et en général toutes les matières animales et végétales en putréfaction, reportent sur d'autres corps l'état de décomposition dans lequel elles se trouvent elles-mêmes; le mouvement qui, par la perturbation d'équilibre, s'imprime à leurs propres éléments, se communique également aux éléments des corps qui se trouvent en contact avec elles."

This explanation seemed to apply to all fermentations besides the alcoholic one, and was for that reason favourably received by many; some, indeed, thinking that all fermentations were fundamentally alike, and that the different products were due to the degree of the alteration of the decomposing substance.

This view led to the idea that the action of the yeast was not due to its vital processes, but rather to a decomposition of its proteid constituents regarded simply as nitrogenous substance.

A third hypothesis was advanced by Berzelius, who thought that fermentation is a contact action due to a catalytic force. This idea has met with very little support.

Pasteur's biological explanation of the action of yeast gradually made itself accepted, even to a certain extent modifying Liebig's position. The latter chemist, in his later writings, while adhering to his theory of a molecular vibration, insists that it is not antagonistic to Pasteur's views, but that the movement is set up by the organisms in the course of their vital activity.

The dependence of alcoholic fermentation on the presence of yeast in a living and active condition seemed, so far as the earlier observers went, to be absolute, and the power of the organism to bring it about appeared to indicate a special property of the yeast cell. The question, however, was soon raised whether or no this property was shared by other organisms than this simple one; whether, in fact, it was not rather a manifestation of certain powers of vegetable protoplasm when placed under abnormal conditions. Reasons for holding the latter view were soon forthcoming.

In 1869 MM. Lechartier and Bellamy published an account of some experiments made with ripe fruits, which they kept for several months in the absence of oxygen. They found that under these conditions the fruits gave off continuously a certain quantity of CO_2, and that at the end of the experiment the pulp contained a measurable quantity of alcohol. Microscopic examination of the pulp showed it to be free from any yeast cells. These observations were shortly afterwards confirmed by Pasteur.

In speculating as to the part which these fermentative processes play in the life of the vegetable cell, Pasteur came to the conclusion that the fermentative power was connected with nutrition in the absence of free oxygen, and that the effort to obtain oxygen under these conditions led to the decomposition of the sugar. He strengthened himself in this opinion by experiments on the cultivation of yeast in the absence of free oxygen, carried on side by side with others in which the gas was supplied freely to the organism. In these experiments he found that the relative weights of yeast formed and sugar decomposed were very different under the two conditions. When no oxygen was supplied, fermentation was very slow, and for one part of yeast formed 60 to 80 parts of sugar disappeared. When oxygen was admitted the fermentation was very rapid, but for one part of yeast formed not more than 4 to 10 parts of sugar were decomposed. This difference was not due to any weakening of the energy of the yeast in the second case, for when some of it was removed and made to act on sugar in the absence of oxygen, it behaved just as did that which was used in the first experiment.

In this way Pasteur was led to hold that fermentation is a kind of intra-molecular respiration, a view which, however, was not allowed to pass without challenge.

Schützenberger argues against it with some force, pointing out at the outset that there seems to be a contradiction between the facts and Pasteur's inferences. In the presence of free oxygen we have a very active fermentation set up, while the yeast is said to possess less fermentative power. Schützenberger claims that the fermentative power is not the same thing as the power of growth, nutrition, and multiplication; that it is a distinct quality which exists in the yeast cells so long as they are living, but is not directly related to the respiratory process.

He bases his view on experiments carried out to ascertain how respiration is affected under changed conditions. The results he obtained were briefly the following:—

(1) In a watery liquid without sugar, but containing oxygen in solution, the quantity of oxygen absorbed in unit time by a gramme of yeast is constant, whatever proportion of oxygen is present.

(2) In a saccharine liquid, containing also albuminous matter, and with oxygen in solution, the same result is obtained, except that the quantity absorbed in unit time is greater.

(3) In two digestions, carried on side by side for some time, one being supplied continuously with oxygen and the other deprived of it, the former produced most alcohol.

If the decomposition of the sugar had been the result of the respiratory activity of the yeast cells at the expense of the combined oxygen of the sugar, it would seem that fermentation should either not have taken place at all in the presence of free oxygen, or that it should have been much less than in the other case, whereas the reverse is what is found.

Hence, Schützenberger comes to the conclusion that the sugar is alimentary and not respiratory.

Pasteur's theory has also found a powerful opponent in Naegeli, who held views much like those advanced by Liebig, Willis and Stahl. He thought that the decomposition of the sugar is brought about by vibrations of the plasma molecules, transferred to the fermentable substance, and that it takes place to a small extent only inside the cells, but to a much greater one in the liquid outside them.

A great development of our knowledge of the details of fermentation has taken place during the last twenty years, due in large measure to the labours of Hansen. Prior to 1878 much uncertainty prevailed concerning the true Saccharomycetes. By most laborious and careful cultivation, an acquaintance has been made by him with the life-history and mode of behaviour under various conditions of six definite species of these fungi. Other investigators have described other species, and a copious literature has sprung up on the subject.

Another fact of importance has also been ascertained which explains the discrepancies of analysis observed so long ago by Gay-Lussac, Dumas and others. It was mentioned above, that the composition of the fermented sugar as computed from the measurement of the CO_2 and alcohol it furnished, must be expressed by the formula $C_6H_{12}O_6$, while the analysis of cane-sugar showed it to be $C_{12}H_{22}O_{11}$. Dumas suggested that it took up water during the alcoholic fermentation. It is now known that this hydrolysis takes place before such a fermentation begins, and that it is set up by a special enzyme which can be extracted from yeast. If a watery extract be made of yeast pressed till nearly or quite dry, the cells give up to the solvent a body which has been called *invertin* or *invertase*. When a liquid containing this is added to a solution of cane-sugar, the latter is found to be very rapidly split up according to the equation

$$C_{12}H_{22}O_{11} + H_2O = C_6H_{12}O_6 + C_6H_{12}O_6.$$

Two sugars are formed, one of which rotates a beam of polarised light to the right, the other to the left. These, which were on this account termed *dextrose* and *levulose* respectively, are now known as *glucose* and *fructose*. These two sugars are those which undergo the alcoholic fermentation, while the cane-sugar itself is incapable of so behaving. The extract of the yeast can carry out the hydrolysis without the cells themselves being present.

More recently still, the sugar *maltose*, which is the product formed by the action of diastase on starch, and which is consequently always present in malted grain, has been ascertained to undergo a similar hydrolysis to cane-sugar, but to yield two molecules of glucose in consequence. The enzyme which causes this hydrolysis is also present in the malt. It is called by some writers *glucase*, by others *maltase*.

Fischer states that such an hydrolysis is necessary in the case of all polysaccharides, or sugars with the empirical formula $C_{12}H_{22}O_{11}$. Thus the sugars which are immediately capable of giving rise to alcohol are especially glucose and fructose; those which are commonly found in the liquids which are fermentable being, in addition, cane-sugar and maltose. The latter always undergo conversion or hydrolysis, and form one or both of the former.

The course of action on mixtures of these sugars in the presence of different species of yeast is often very different. Thus Hansen's six true species of Saccharomycetes, all hydrolyse both cane-sugar and maltose, besides carrying on alcoholic fermentation of their products. *S. Marxianus* differs in not attacking maltose, while *S. membranæfaciens* ferments none of them, and does not contain invertase. Other organisms have similar idiosyncrasies.

Fischer advances a hypothesis to explain this great variety of action, which throws a great deal of light on the subject. Recognising, as it is now possible to do, that different sugars have different molecular configurations, he suggests that the fermentative principle of the yeast, whatever it may be, must possess a corresponding or complementary configuration, and so be able to come into very close relation to the molecule of the sugar it ferments, much as a key can only unfasten a lock for which it is constructed and to whose parts its own shape corresponds. The configuration of the two fitting as it were into each other, the disruption of the sugar molecule by the action or possibly vibration of the fermentative principle becomes conceivable.

Fischer does not base this hypothesis upon supposition merely, but has tested it by studying the action of some of the soluble enzymes upon the bodies they attack. His results with invertase are very interesting. According to Van 't Hoff's stereochemical theory, there are possibly to be found two methyl-glucosides, α and β, which differ only in their configuration. Fischer synthesised both these bodies and heated a quantity of each with 20 times its volume of invertase solution to 30–33° C. At the end of some time about half of the α body was hydrolysed, yielding glucose as one of its products. The β body underwent no change. Yet the two methyl-glucosides have the same composition, are formed from the same alcohol (methyl alcohol) and from the same sugar (glucose), and differ only in the configuration of a single carbon atom rendered asymmetric by the introduction of the methyl group into the sugar.

The great advances made in the study of fermentations under the action of soluble enzymes during late years, has drawn the attention of many to the possibility of the secretion of an alcohol-producing enyzme by the yeast cells. It is evident that the introduction of the idea of an enyzme need not involve a new view as to what fermentation itself is. It is only necessary to substitute the secreted enzyme for the protoplasm of the cell, as the active agent in the process.

The idea was advanced some time ago by Berthelot, who compared both lactic and alcoholic fermentations to the conversion of starch into sugar. It has also been suggested by Moritz Traube and by Hoppe-Seyler.

The enyzme has, according to Buchner, actually been prepared from very active yeast by grinding the cells and squeezing the fluid contents from the resulting mass under the very heavy pressure of 500 atmospheres to the square inch.

As a review of Buchner's work appeared in this journal comparatively recently, it is not necessary to recount his experiments in detail.

The discovery, should it be confirmed, deals a very heavy blow to the vibration theories of fermentation due to Liebig and Naegeli. Their views are only tenable on the theory that most, if not all, of the action takes place in the liquid outside the cells. If Buchner is correct, and the work is done by means of an enzyme, it must necessarily be *intra-cellular*, for enzymes, so far as they have at present been investigated, show no tendency to diffuse through such a membrane as the cell wall. It also militates against Pasteur's theory of intramolecular respiration, which demands the idea of the decomposition being brought about by chemical action between the protoplasm and the body from which it, according to the theory, obtains its oxygen.

J. Reynolds Green.

THE METALS USED BY THE GREAT NATIONS OF ANTIQUITY.[1]

At the beginning of this century little was known of the great nations of antiquity, except through the classic poets and historians, and the sacred writings of the Hebrew people. Since then our knowledge has been enormously increased by the labours of scholars and explorers; the ruins of ancient cities have been exhumed, and the contemporary literature of Egypt and Assyria, inscribed on papyri or tablets of clay, and painted or carved on the walls of temples, palaces and tombs, has been deciphered. What is in some respects still more important is, that objects found in these ruins have thrown great light upon the daily life of the people, and their ornamental and useful arts. One of the departments of this inquiry concerns the metals used by the different nations, and at the different epochs of their history; and it is to this that my attention will be confined this evening. The difficulty I experience is the vast amount of material; and I cannot attempt anything more than a general view of the subject, and some of the most salient points.

The area over which the inquiry extends is that of the lands bordering on the eastern half of the Mediterranean, and stretching eastwards to the Persian Gulf. The time, so far as Egypt is concerned, includes the whole period from the first Pharaoh, Menes, to the conquest of the country by Alexander the Great; ranging from about B.C. 4400 to B.C. 332. The chronology employed throughout is that of Dr. Wallis Budge, of the British Museum, who has adopted in the main that of Brugsch Bey. This period of 4000 years appears to me reasonable, and errs, if anything, on the side of moderation. Our knowledge of the other nations does not extend to anything like so remote a time.

Egypt.

If we take as our starting-point Seneferu's triumphal tablet in Wady Maghara, in the Sinaitic peninsula, we see the king flourishing his battle-axe over the head of his enemy. This symbolises the conquest of the copper and turquoise mines of that region, and implies, of course, their previous existence as a source of wealth. In the hieroglyphic inscription above his head there is not only the king's name spelt phonetically, but in the royal titles are seen two ideographs which bear upon our subject. One is the necklace or ornamental collar which is the well-known symbol for gold; and the other an axe, the head of which resembles rather that of a copper than of a stone weapon. These titles have no reference to the metals themselves, but mean "Golden Horus" and "Beneficent Divinity." Before such symbols could be used to express abstract ideas, they must have been well known in their concrete form. The date assigned to Seneferu is B.C. 3750; but the discoveries of the past year have put in our possession the actual metals themselves, of a much greater antiquity. M. de Morgan, late Director General of Antiquities in Egypt, has explored an enormous royal tomb at Nagada, the centre chamber of which contained the mummy of the Pharaoh, with the cartouche of King Menes, the reputed first King of Egypt. If it be really his tomb, the probable date will be B.C. 4400. What is interesting to us is that in two of the chambers, among a multitude of articles made of ivory, quartz, porphyry, wood, alabaster, tortoiseshell, mother-of-pearl, obsidian, earthenware, cornelian, glass and cloth, there were found some small pieces of metal, viz. two or three morsels of gold, and a long bead of that metal of a somewhat crescent form, together with some articles of copper—a kind of button, a bead, and some fine wire. The button was analysed by M. Berthelot, the well-known French chemist and politician, to whom we are indebted for the examination of a very large number of ancient metallic objects; he states that it is nearly pure copper, without arsenic or any other metal in notable proportion.

These are the oldest metallic objects in the world to which we can assign a probable date. But Prof. Flinders Petrie had discovered, three years ago, also at Nagada, a great number of objects of the same character, and among them a few small copper implements. Some filings from a dagger, a celt, and a little harpoon were analysed by me, and found to consist of practically pure copper, without any trace of tin. The remains of these filings are in the little bottles on the table. The age of these tools must be comparable with that of the royal tomb, and may possibly be even older.

Of about the same period, and perhaps even earlier, are a number of tombs at and near Abydos, which have been explored by M. Amélineau, bearing the names of kings unknown to history, accompanied by hieroglyphics of archaic form. In these have been found larger quantities of copper utensils, viz. pots, hatchets, needles, chisels, &c., which M. Berthelot also finds to be nearly pure metal, but some contain a little arsenic. It would appear, therefore, that the Egyptians, at the very beginning of the historic period were acquainted with the use of gold and copper. Let us follow the history of these two metals, beginning with gold, which, as it is generally found native, was probably the first known to man.

According to a letter just received by me from M. Berthelot, all or nearly all the ancient gold that he has examined contains more or less silver. This pale coloured gold is sometimes termed electrum, and was found in great quantity in Asia Minor, where the Pactolus and other streams "rolled down their golden sands." Gold is frequently represented in the Egyptian sculptures and pictures; for instance, in the very interesting scenes of social life at Beni Hassan, *circa* B.C. 2400, illustrations of which I now throw upon the screen, we see the goldsmiths making jewellery, weighing out the metal, melting it in their little furnaces with the aid of blowpipe and pincers, washing it, and working it into the proper forms. In the picture of a bazaar at Thebes we find a lady bargaining for a necklet; and in another picture we see the weighing of thick rings of gold and of silver, which were used as articles of exchange. I wish I could show you the exquisite gold jewellery, inlaid with gems, found in the tombs of four princesses buried at Dahshur, about B.C. 2350, and which is now exhibited in the museum of Gizeh; but I can throw upon the screen the photograph of the beautiful enamelled gold necklace of Queen Ahhotpu, B.C. 1700. The great kings Seti I. and Rameses II., B.C. 1300, worked extensive gold mines in Nubia, which yielded gold free from silver.[1]

---

[1] A Friday evening discourse delivered at the Royal Institution, on February 11, by Dr. J. H. Gladstone, F.R.S.

To return to the history of copper. In the inscriptions we cannot distinguish between copper and its various alloys, for they are all expressed by the general term *chomt*, and the symbol of the battle-axe blade. But if we can get the substance itself and analyse it, we know what we are dealing with. Many specimens of copper implements dating from the fourth to the sixth dynasty, say from B.C. 3750 to 3100, have been examined. They consist of almost pure copper. One of the earliest, analysed by me, was a piece of a vessel from El Kab, which contained 98 per cent. of copper, the remaining 2 per cent. being made up of bismuth, arsenic, lead, iron, sulphur, and oxygen, evidently the impurities in the original ore.

It was evidently very important for the Egyptians to harden the copper as much as possible; and this might be effected in several ways: (1) by hammering, (2) by the admixture of arsenic, (3) by the admixture of tin, (4) by the admixture of zinc, (5) by the presence of a certain amount of oxygen in the form of cuprous oxide. As to arsenic, some of the oldest copper implements contain a notable quantity. Dr. Percy found 2·29 per cent. in a knife which was dug up some distance below a statue of Rameses II.; and I found 3·9 per cent. in a hatchet from Kahun, dating back to B.C. 2300. It is said, however, that the addition of 0·5 per cent. of arsenic is sufficient to produce a hardening effect; and many specimens of ancient copper implements contain this amount, though the proportion of arsenic in copper ores themselves rarely exceeds 0·1 per cent.

As to the mixture of tin. It is well known that bronze, the alloy of copper and tin, is stronger than pure copper. The extent of this depends upon the proportion of the two metals, and probably on other circumstances. The oldest supposed occurrence of an admixture of tin is in a bronze rod found by Flinders Petrie in a mastaba at Medum, probably of the fourth dynasty, which I found to contain 9·1 per cent. of tin. It seemed so improbable that tin should be employed at so remote a period, and that in sufficient quantity to make what we call gun-metal, that I was suspicious of its genuineness, notwithstanding the very circumstantial account of its discovery; but M. Berthelot has since found in a ring from a tomb at Dahshur, believed to be not much later than the third dynasty, 8·2 per cent. of tin; and in a vase of the sixth dynasty, 5·68 per cent. of tin. These seem to restore the credit of Dr. Petrie's specimen. At a later period weak bronzes become common. Thus, at Kahun tools found in a carpenter's basket by Prof. Petrie contained varying amounts of tin from 0·5 to 10·0 per cent.; 6 or 7 per cent. of tin was subsequently common. Bronze implements abound in Egypt. I am able not only to throw upon the screen representations of arrow- and spear-heads and battle-axes, but, through the kindness of Sir John Evans, to show a beautiful large spear-head with an inscription of King Kames (B.C. 1750) down the blade. I am also indebted to Prof. Flinders Petrie and Dr. Walker for this collection of implements of the twelfth dynasty from Illahun, including a fine mirror with ivory handle, necklets, and a bronze casting for a knife which was never finished; also many objects of the eighteenth dynasty, or thereabouts, such as a sword, dagger and axe, together with mirrors, bracelets, earrings and pendants, and a steelyard. My own collection contains specimens of what are believed to be razors of different types, and small statuettes.

As to the admixture of zinc. There does not seem to be any specimen of brass, properly so called, found in Egypt within the period of our inquiry; but various attempts are known to have been made to imitate gold, of which aurochalcum is an instance, and that may have been yellow brass.

As to oxygen. It is generally supposed to exist in copper in the form of the red cuprous oxide; and most of the copper, and many of the bronze, implements have a covering of this substance. This is caused by the gradual formation of an oxychloride of copper through the action of alkaline chlorides in the soil, aided by the air and moisture. Berthelot has worked out the chemistry of this substance very fully, and shows how when once formed it gradually works its way into the solid metal, transforming it into the suboxide, and frequently disintegrating it. Some good specimens of little bronze images suffering this disintegration are exhibited by Mr. Joseph Offord. Two at least of the copper adzes on the table consist to the extent of 30 or more per cent. of oxide of copper; they are exceedingly hard, and it becomes a question whether the formation of the oxide is due to the slow chemical change, or whether it was purposely produced in the manufacture in order to harden them. The effect of different proportions of oxygen on the tenacity of copper is known to be very various, and certainly deserves further investigation.

It is difficult, or rather impossible, to express in definite figures the advantage gained by the ancient Egyptian metallurgists through this alloying of the copper. Arsenic, tin, or zinc may and do affect the hardness or the tenacity, or the elasticity, in different ways, and also according to the proportion of the metal united with the copper. Thus there are several very different kinds of alloys of copper and tin, though they are all included under the name of bronze; moreover, a piece of copper which has been exposed to a considerable stress is permanently altered in its properties. Again, in any table of numerical values it should be taken into account whether the copper with which the alloys are compared had been made as pure as possible, or contained a normal amount of oxygen.[1] We must rest contented with the knowledge that copper can be rendered stronger and more serviceable by these means, and that the ancient artificers were acquainted with the fact.

After the extensive use of copper and bronze in ancient Egypt, other metals were gradually employed. Silver, as distinct from electrum, seems to have been little used, except for ornamental purposes.[2] The diadem of one of the kings named Antef (B.C. about 2700), and that of the Princess Noubhotep (B.C. 2400), were made of silver and gold. Silver also occurs among the beautiful jewellery of the princesses buried at Dahshur, and that of Queen Ahhotpu. But when the intercourse between Egypt and the neighbouring nations of Asia was better established, silver became much more common; thus we find it frequently mentioned in the Great Harris papyrus (B.C. 1200), in which the King Rameses III. describes his magnificent presents to the temples and priesthood of Egypt. The metal lead also occurs frequently in the same lists, and was used, as elsewhere, for mixing with copper and tin in the formation of the easily fusible bronze used for statuary.

Tin has a more interesting history. We have found it used in combination with copper as far back as perhaps B.C. 3400, and enormous quantities of it must have been afterwards employed. It is still a question whether in the first instance some stanniferous copper ore was used, or whether the Egyptians found that the addition of a certain black mineral was advantageous for hardening their copper, or whether from early days they reduced the metal from its ore and added it to the copper in the furnace. That, at any rate, they were afterwards acquainted with the metal itself, is clear from the discovery by Flinders Petrie of a small ring at Gurob (B.C. 1450), which, on examination, I found to be of tin, imperfectly reduced from its ore. Berthelot has also analysed what was essentially a tin ring, though alloyed with copper, dating about a century later; and Prof. Church describes a scarab of the same metal, which was found on the breast of a mummy of about the seventh century B.C. This metal also appears more than once among the rich gifts catalogued on the papyrus of Rameses III., if "*tehi*" is to be so translated.

Although kohl, the sulphide of antimony, was used for blackening the eyebrows from a very early period, I am not aware of any metallic antimony in Egypt of older date than some beads found by Prof. Petrie at Illahun in a tomb of about 800 B.C. They proved to be fairly pure metal. It is curious that the art of preparing this metal was afterwards lost, and only rediscovered in the fifteenth century of our era.

---

[1] Since the lecture was delivered the Egypt Exploration Fund has issued a memoir, under the title of "Deshasheh," from which it appears that in the very ancient tombs at that place there were found a few gold beads and copper objects, and a picture of an artificer weighing a copper bowl.

[1] For tabulated results of experiments bearing on these points, see "The Testing of Materials of Construction," by Prof. Cawthorne Unwin; and the second Report to the Alloys Research Committee of the Institution of Mechanical Engineers, by Prof. Roberts-Austen, with the discussion thereon.—*Proc. Inst. Mech. En.*, April 1893.

[2] In the translation of "The Book of the Dead," by Dr. Wallis Budge, vol. iii., published since the lecture, it appears that in one of the oldest chapters, said to have been found by Herutataf, about B.C. 3600, there is a formulary to be said over a scarab of greenstone encircled with a band of refined copper, and having a ring of silver.

The period of the first use of iron in Egypt is at present a matter of great controversy. Some contend for its use even in the mythological period, while others would bring it as late as 800 or 600 B.C. There exist the oxidised remains of some wedges of iron intended to keep erect the obelisks of Rameses II. at Tanis, which is near the border of Palestine; but there is no positive proof that they were placed there during his reign. I have little doubt, however, that the Black *Baa*, mentioned several times in the Harris papyrus, B.C. 1200, is the same as the *μελας σιδηρος* of Hesiod; *i.e.* iron. In the long account which King Piankhi gives of his invasion of Egypt from the Upper Nile, he mentions iron more than once among the presents made to him by the minor chieftains of the time in token of their submission, indicating that at this period, B.C. 700, it was still not very common.

Assyria.

In the country lying between or near the Euphrates and the Tigris we have some antiquities dating, perhaps, as far back as any in Egypt. We have also a great amount of Accadian and Assyrian historical and other literature on tablets and cylinders of clay, and on the walls of the great palaces and temples. As in the case of Egypt, the discoveries of the remotest age are those which have been most recently published. Dr. Peters has just given us the records of the explorations of the American Oriental Society at Nippur, and describes the successive layers of the great temple of Bel. These appear to indicate the absence of metal in very remote periods. The oldest specimens are those recently found by M. de Sarzec at Tello (Lagash) in Southern Chaldæa. They consist of some votive statuettes, and a colossal spear, an adze and curved hatchet, all of copper without tin, according to M. Berthelot's analysis. A small vase of antimony, and a large one of silver have also been found. The period of these is supposed to be some considerable time anterior to B.C. 2500. At Tel el Sifr, in the same neighbourhood, Mr. Loftus discovered a large copper factory, in which were cauldrons, vases, hammers, hatchets, links of chain, ingots, and a great weight of copper dross, together with a piece of lead. The date of these is believed to be about B.C. 1500. At Nippur the American explorers found at a higher level, in the temple of Bel, what they term a jeweller's shop, which consisted of a box full of jewellery, mainly precious stones, but also containing some gold and copper nails; these apparently date from about B.C. 1300. In Babylonian graves and other places of about the same period there have been found objects made of copper and iron and silver wire; but the use of metals seems much more restricted in these great alluvial plains than in contemporary Egypt. Iron, however, was perhaps an exception. According to Messrs. Perrot and Chipiez, excavations at Warka seem to prove that the Chaldæans made use of iron sooner than the Egyptians; in any case, it was manufactured and employed in far greater quantities in Mesopotamia than in the Nile Valley; in fact, at Khorsabad M. Place found hooks and grappling irons, fastened by heavy rings to chain cables, picks, mattocks, hammers, ploughshares, &c., in all about 157 tons weight. Mr. Layard also found at Nimroud a large quantity of scale armour of iron in a very decomposed state, but exactly resembling what is represented in the sculptures of warriors. Of this he collected two or three basketfuls.

Coming down to the period of the great Babylonian Empire, we find very large treasures of the precious metals changing hands during their sanguinary wars. Thus, on the black obelisk of Shalmaneser II. in the British Museum, we have depicted the embassies from different nations bringing their tribute to the feet of the king; the second of these has an inscription reading: "The tribute of Jehu, son of Omri; silver, gold, bowls of gold, vessels of gold, goblets of gold, pitchers of gold, lead, sceptres for the king's hand, and staves; I received." The gates of his palace at Balawat, now at the British Museum, were of stout timber strengthened with bands of bronze, and the Trustees kindly gave me a small piece of the metal for analysis; it yielded about 11 per cent. of tin. The grandson of this king, Rimmon Narari III., probably B.C. 797, took Damascus, and the spoil, according to the inscriptions, comprised 2300 talents of silver, 20 of gold, 3000 of copper, 5000 of iron, together with large quantities of ivory, &c.

Lenormant gives two verses of a magical hymn to the god Fire, which exist both in Accadian and Assyrian; they run—"Copper, tin, their mixer thou art; gold, silver, their purifier thou art."

Palestine.

Between the great territories o. Egypt and Assyria lies a narrow strip of country, small in extent, but very important in the history of civilisation, commerce and religion. During the period of which we are speaking it was occupied by a succession of different nations. It formed part of the possession of the great Hittite people. We cannot read their inscriptions, and we know little of their history. We have, however, bronze and silver seals that are supposed to belong to them, and curious bronze figures. They seem to have had abundance of silver, probably from the mines of Bulgardagh in Lycaonia. We read of Abraham purchasing a piece of land from Ephron the Hittite for which he weighed out "four hundred shekels of silver current money with the merchant." He was, in fact, rich in silver and gold, and among the presents given to Rebekah were jewels of silver and jewels of gold.

The first notice of metals in Palestine to which we can give an approximate date is in connection with the invasion of that land, and other countries further to the eastward, by the great Egyptian King Thothmes III. He led his army through the plain of Esdraelon, and gained a victory at Megiddo, and amongst the spoil were chariots inlaid with gold, chariots and dishes of silver, copper, lead, and what was apparently iron ore. This took place about B.C. 1600. The original of the long treaty of peace and amity between Katesir, King of the Hittites, and Rameses II. is said to have been engraved on tablets of silver.

When the Children of Israel left Egypt they were, of course, acquainted with the metals used in that country. They borrowed the jewels of silver and gold of their oppressors; and of these the golden calf was afterwards made. We read, too, of the "brazen serpent,"[1] and of elaborate directions for the use of silver, gold, and brass in the construction of the Tabernacle. Lead is mentioned once, but iron seems to have been unknown to them, the word never occurring in the Book of Exodus; and though it is occasionally mentioned in the later Books of Numbers, Deuteronomy and Joshua, it is always with reference, not to the Israelites, but to the nations they encountered. Thus we read of the Midianites having gold, silver, copper, iron, tin and lead, which were to be purified by passing through the fire; of the King of Bashan, a remnant of the Rephaim, who had the rare luxury of an iron bedstead, which was kept afterwards as a curiosity at Rabbah; and of the spoil of the Amorite city of Jericho, comprising gold, silver, copper and iron. Later on the Canaanites were formidable with their "nine hundred chariots of iron"; and later still the Philistines, whose champion, Goliath of Gath, was clad in armour of bronze, and bore a spear with a heavy head of iron. Among the materials collected by David in rich abundance for the building of the Temple were gold, silver, bronze and iron; but the best artificers in metals were furnished by Hiram of Tyre, at the request of Solomon. During the reign of the latter there was an immense accumulation of these precious metals in Jerusalem. The comparative value of the different materials is indicated by the words of the prophet in describing the Zion of the future, "for brass I will bring gold, and for iron I will bring silver, and for wood brass, and for stones iron" (Isaiah lx. 17). Another prophet (Jeremiah vi. 29, 30) uses the simile of the refining of silver by the process of cupellation.

The great mound of Tel el Hesy affords a very perfect example of the débris of town upon town during many centuries; and of the light that these mounds throw upon the progress of civilisation. When Joshua, after the decisive victory of Beth-horon, led his troops to the plain in the south-west corner of Palestine, he besieged and took Lachish, a city of the Amorites. It then became an important stronghold of the Israelites: its vicissitudes are frequently mentioned at various dates of the sacred history, as well as on the Tel el Amarna tablets. The mound has lately been explored by Messrs. Petrie and Bliss; and in the remains of the Amorite city (perhaps B.C. 1500) there are large rough weapons of war, made of copper without admixture of tin; above this, dating perhaps from 1250 to 800, appear bronze tools, with an occasional piece of silver or lead, but the bronze gradually becomes scarcer, its place being taken by iron, till at the top of the mound there is little else than that metal. The Palestine Exploration Fund has kindly lent me specimens of these finds for exhibition. About B.C. 700,

---

[1] The word "brass" at the time of the translation of our Bible was used indiscriminately for copper or any of its alloys. In the Old Testament it never refers to the alloy of zinc, to which the term is now confined.

Lachish was the headquarters of Sennacherib, during his invasion of Palestine. From it he sent his messengers to Hezekiah, and at the same town he received the peace offering of the Jewish king, 300 talents of silver and 30 talents of gold, to raise which he had to despoil his palace and the Temple. In Sennacherib's own version of the transaction, the silver is given as 800 talents, and the gold 30. Lachish was finally deserted about 400 B.C.

Greece.

We know little of the very early history of Greece, for the most ancient monuments bear no inscriptions, and literature did not commence till the time of the Homeric poems. In these, and in Hesiod, there are many graphic descriptions of the habits and arts of the heroic period, including the use of metals; and many of the towns described in them have recently been explored with great success, and have yielded up the very materials about which they sang.

Probably the earliest find has been in the volcanic island of Santorin, where, under beds of pozzolana, which are supposed to date about 2000 B.C., have been found two little rings of beaten gold and a saw of pure copper. In the Ashmolean Museum there are a very ancient silver ball, and beads of the same metal rolled from the flat; also a spear-head of copper. These were obtained from Amorgos. In Antiparos there have also been found very ancient objects of silver mixed with copper.

Passing to the mainland, the towns of the Peloponnesus and the mound of Hissarlik, the supposed Troy, have been explored by Dr. Schliemann, Dr. Tsountas, and Dr. Dorpfeld; and they reveal what is termed the Mycenæan period, which figures so largely in the poems of Homer and Hesiod. In these the precious metals, gold and silver, are constantly mentioned, together with χαλκος, generally translated brass. Thus, in the description of Achilles' shield, we are introduced to Hephaistos at his great forge on Etna, heating the bars of silver, or brass, or tin, or gold, and then hammering them on the anvil, so forming the designs which represent so beautifully the various scenes of peace and war. After having fashioned the shield, he is represented as forging for the warrior a cuirass of copper, greaves of tin, and a helmet with a golden crest.

Homer frequently mentions iron, but generally gives it the epithet "worked with toil," and treats it as a rare and costly metal. Thus a huge iron discus was given as a valuable prize to the hero who could throw it the farthest in the athletic games at the funeral of Patroclus.

Mr. W. E. Gladstone, who has long turned the great powers of his mind from time to time to Homeric studies, wrote me last summer: "The poems of Homer showed me, I think, forty years ago that they represented in the main a copper age." The reasons he assigns in his letter, as well as in his published works, are fairly conclusive, and the recent explorations, and the analyses of Dr. Percy, Prof. Roberts-Austen, and others, have shown that in the early period of the Mycenæan age copper without tin was employed for numberless purposes; but as time advanced, bronze came into use. At Hissarlik, in the lowest and second city have been found a gilded knife-blade, needles and pins, of practically pure copper; while in the third and sixth cities occur battle-axes of copper containing 3 to 8 per cent. of tin. In the very old town of Tiryns, the palace apparently had its walls covered with sheets of copper; much lead was also found there. At Mycenai, the Achaian capital, the metals in use were gold, silver, copper, bronze and lead; copper jugs and cauldrons are common, and great leaden jars for storing grain; also elegant bronze tools and cutlery; mirrors, razors and swords. In the tombs the bodies are laden with jewels, largely ornaments of gold, with a much smaller amount of silver.

Some of these objects illustrate the poems of the time; thus, in the Odyssey we find Nestor making a vow to Athenæ: "So the heifer came from the field; . . . the smith came holding in his hands his tools, the means of his craft, anvil and hammer, and well-made pincers, wherewith he wrought the gold. Athenæ, too, came to receive the sacrifice. And the old knight Nestor gave gold, and the other fashioned it skilfully, and gilded therewith the horns of the heifer, that the goddess might be glad at the sight of her fair offering." Now at Mycenai there was found the model of an ox-head in silver, with its horns gilded, and between them a rosette of gold, not directly attached to the silver, but to a thin copper plate. In Vaphio, a town near Sparta, of a somewhat later period, tombs were found containing many beautiful objects in silver, gold and bronze. Especially noteworthy are two golden cups embossed with figures of bulls and men; in the one case it is a spirited hunt in the woods, in the other a peaceful scene on the meadows. Iron, in Mycenai, appears only as a precious metal of which finger-rings are formed.

In the remains of a Greek colony in Cyprus, belonging to the end of the Mycenæan period, which is now being explored by the British Museum, iron plays a much more important part. At Athens also large iron swords, which belonged to the ninth or tenth century B.C., have been found in an old cemetery.

After this came the intellectual period of Grecian history. Aristotle must be mentioned in any account of the science of the day; and he it is who gives us the first description of the metal mercury, and also how to produce the alloy which we call brass, by heating together copper and calamine, the carbonate of zinc. Metallic zinc, however, was not known for many centuries afterwards.

Conclusion.

In tracing back the history of these great nations we have found evidence of a time when metals were little, if at all, employed: the potter's art was well known, and early man became wonderfully proficient in working hard stone, and especially flint. The earliest indications we have of metals are of gold and copper, both being scarce, and no doubt costly. Gold was probably the earliest to attract the attention of mankind, because it occurs native, of bright yellow colour, and is easily worked. Copper, however, dates to a similar period, so far as the remains which have come down to us are concerned. Probably the deep blue carbonate, such as occurs in Armenia, was first worked. When silver was first used is not very evident, but it is certain that it was far more common in the northern portion of the area we have been considering, than in the southern. The metallurgy of copper was doubtless a matter of much study and experiment, so as to produce the hardest metal. This seems to have led to the discovery of tin, but at what precise period we know not; nor do we know whether it was brought from Etruria, or found in some nearer region. Mines of tin were certainly worked at Cento Camarelle, as Egyptian scarabs have been found in the old workings,[1] and near Campiglia and in Elba, as well as in the Iberian peninsula. This search for the metals, and the necessity of carrying the ore or rough metal to the places where it was wrought, or of the finished material to distant customers, must have greatly promoted commerce. This took place both by land and sea, in caravans and ships. In this way tools and other objects were disseminated through the more distant parts of Europe and Asia: the similarity of type over large areas shows a common origin, and hence we can even roughly form an opinion as to whether they were introduced in earlier or later times. Thus, in Switzerland and Scandinavia we meet with copper implements as well as bronze, and ancient as well as modern forms; while in Britain we find no evidence of copper tools, though bronze objects are abundant.

The Phœnicians, arriving on the eastern shores of the Mediterranean from the direction of the Persian Gulf, formed an important nation for about 1000 years, from B.C. 1400 to B.C. 400. They were great artificers, but not having much originality they adopted the patterns and designs of Egypt or Assyria. They were also pre-eminently traders, and founded cities and emporia of commerce, so that their metal work was spread over all the Mediterranean. It is to be found in Cyprus, mixed with the workmanship of the Grecian Mycenæan age. Their ornamental jewellery was eagerly sought in Etruria, Greece and Calabria; for the beauty of it I may refer you to the Etruscan cup of gold in the South Kensington Museum, and the wonderful work in gold in one of the Greek rooms in the British Museum.

Commerce implies a large extension of a medium of exchange. The whole question of money is far too wide a subject for us to deal with now; suffice it to say that Herodotus attributes to the Lydians the introduction of the use of coins. The earliest were of electrum, issued in the form of oval bullets, officially stamped on one side. They date back, perhaps, to B.C. 700; but according to other authorities, silver money was coined at Ægina more than a century before that time.

The great period which has been under our consideration terminated in each country with an age of disorder and deterioration. The rise of the Roman Empire introduced a new era: it was in one sense an iron age—*ferrum* being synonymous with the sword. We now live in another kind of iron age, but in better and brighter times than those of Hesiod, and we may hope that our great engineering works, our iron roads and iron steam-ships may lead not to the enslaving but the brotherhood of nations.

---

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Miss Jane Cruikshank has given 15,000*l.* to Aberdeen University, to provide a botanic garden at Aberdeen in memory of the late Dr. Alexander Cruikshank.

The University of Edinburgh has conferred the honorary degree of LL.D. upon Mr. Horace T. Brown, F.R.S., Prof. D. G. Ritchie, and Prof. J. Victor Carus, assistant professor of zoology at Leipzig.

In order to make accessible under the most favourable conditions to university students, to teachers, and to investigators, the facilities and environment of the Illinois Biological Station, reinforced by the equipment of the biological departments of the University of Illinois, the university has decided to open, on June 15, a summer school of field and laboratory biology at this station on the Illinois River, at Havana. Opportunity is thus given for personal studies, in field and laboratory, of the plants and animals of a peculiarly rich and interesting situation, and of the methods of modern biological station work.

The following are items concerning the extension of provision for scientific training in the United States:—Syracuse University will shortly begin the erection of a 45,000-dollar science building. —Adelbert College at Cleveland, Ohio, has a biological building under way, which will cost about the same amount.—Richmond College, Virginia, has received 5000 dollars towards a science building.—The University of Chicago has received a gift of about 150,000 dollars from an anonymous donor. Miss Gould has given a further sum of 10,000 dollars towards the endowment of the engineering school of New York University.—Mr. Chester W. Kingsley has given 25,000 dollars to Colby University.

It was briefly noted last week that the University of Paris had taken up a loan amounting in all to 1,700,000 francs. Referring to this action, the Paris correspondent of the *Lancet* remarks:—The law which has reconstituted the universities has given to them a civil personality; they have their own budget and their own sources of income, which are definite and assured, and they are able to contract loans on the security of these sources of income. The 1,700,000 francs which the university has borrowed will be devoted to carrying out two schemes. The greater part of this sum will be devoted to the construction of buildings for the accommodation of first-year students in medicine. The other portion of the loan will be devoted to the keeping-up of a laboratory of natural history at Fontainebleau.

The Technical Education Board of the London County Council will proceed shortly to award not less than five Senior County Scholarships. These scholarships are of the value of 50*l.* a year, together with the payment of tuition fees up to 30*l.* a year, and are tenable for three years at university colleges and advanced technical institutes. They are confined to residents within the administrative county of London, and are open only to those whose parents are in receipt of not more than 400*l.* a year. Candidates should as a rule be under twenty-two years of age, though the Board reserves the right to give preference to candidates who are under nineteen years of age. The scholarships are intended to encourage more especially the teaching of science, and to enable those students who cannot afford a university training to pursue advanced studies for a period of three years in the highest university institutions in this country or abroad. Of the seventeen students who are now holding Senior Scholarships five are studying at Cambridge, five at the Central Technical College in Exhibition Road, three at the Durham College of Science, Newcastle-upon-Tyne, two at German Universities, and two (ladies) at Bedford College, and Holloway College respectively. The scholarships are awarded on a consideration of the past record and general qualifications of the candidates, and not upon the results of a set examination. Application forms may be obtained from the Board's Secretary, 116 St. Martin's Lane, W.C., and must be returned not later than Monday, May 16.

During his term of office, Sir A. Mackenzie, the Lieutenant-Governor of Bengal, has done much to advance the cause of scientific and technical education in his province, and a speech he delivered recently at the Indian Association for the cultivation of science is a further expression of his sympathies with the development of education on scientific lines. In the course of his address he said:—"I would have the student of the future cease to be brought up on badly assimilated *words* and on high-faluting rhetoric, and I would have him taught to observe and think, and *educate himself* in the way Herbert Spencer indicates as the great desideratum in all education. The oriental mind is only too prone to rest on authority and accept inaccuracies. Pupils trained on books and books alone are mere passive recipients of other people's ideas. They never learn the arts of observing facts and applying knowledge. The study of science cultivates the judgment as the study of language never can. Science constantly appeals to and develops the individual reason. It is no doubt the case that even in England people are only now waking up to the knowledge of a wise pedagogy, but they *are* waking up at last. The idea of development of faculty is being substituted for that of mere acquisition of knowledge. The mere cultivation of words and application of formulæ is being discredited. The ideal education is being recognised as one which multiplies the power of the eye to see, of the ears to hear, of the hand to execute; which puts a mind well stored with knowledge into active contact with faculties capable of translating it into action." In India at present science holds but a very secondary place in the curriculum of high education, and if the country is ever to advance there must be an educational revolution which will release the youth of India from the bonds of a purely literary education. The University of Calcutta has as yet done little for science culture, but the Bengal Government has within the last few years done good work for the advancement of technical education. The reconstruction of the Medical College begun by Sir Charles Elliott has been pushed on; and the Sibpur Engineering College has been expanded so as to make it a school where civil engineering, mining engineering, mechanical engineering, and electrical engineering can be and are being thoroughly taught to over 300 students. The Presidency College, having as principal Prof. A. Pedler and upon its staff Profs. J. C. Bose and Roy, has also admirable work to show. Sir A. Mackenzie concluded by saying: "As the Bengali has conquered the field of medicine, so he may conquer the field of engineering and mechanical industry, if those engaged in the instruction of the young will only shake themselves free from the trammels of a literary curriculum which, coupled with the absence of moral and religious training and the failure to impart a sound knowledge of their own country, its material wants and capabilities, is in my judgment fast ruining the youth of the country and stunting their development."

SCIENTIFIC SERIAL.

Bulletin of the American Mathematical Society, March.—The relations of analysis and mathematical physics is the translation, by C. J. Keyser, of the interesting address delivered before the International Congress of Mathematicians, at Zürich, on August 9, 1897. The writer, Prof. H. Poincaré, answers some questions which he says are often asked, as "What is the utility of mathematics, and whether its nicely constructed theories, drawn entirely from the mind, are not artificial products of our caprice?" "The end of mathematical physics is not merely to facilitate the numerical calculation of certain constants, or the integration of certain differential equations. It is more; it is, above all, to disclose to the physicist the concealed harmonies of things by furnishing him with a new point of view."—The roots of polynomials which satisfy certain linear differential equations of the second order, is a short note by Prof. M. Bôcher, following up work by Stieltjes in vol. vi. of the *Acta Mathematica*. —Inflexional lines, triplets, and triangles associated with the plane cubic curve, by Prof. H. S. White, considers the configuration of the nine inflexions of a non-singular plane cubic and the twelve lines containing them 3 and 3, from what the writer thinks to be a novel point of view. The statements are of some interest.—On the intersections of plane curves, by Prof. Charlotte Scott, brings together several passages bearing on Maclaurin's paradox (*i.e.* Cramer's so-called, but it is here carried back to Maclaurin). It is a valuable paper on curves and is mainly concerned with a recent paper by F. S. Macaulay, viz. point groups in relation to curves (*London Math. Soc. Proc.*, vol. xxvi. pp. 495–544).—Prof. Beman points out the use of *i*, by Euler, to represent an imaginary, thus disposing of Gauss's claim to priority.—The remaining matter consists of shorter notices (*i.e.* reviews), notes, and publications.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, March 10.—"An Extension of Maxwell's Electro-magnetic Theory of Light to include Dispersion, Metallic Reflection, and Allied Phenomena." By Edwin Edser, A.R.C.S. Communicated by Captain W. de W. Abney, C.B., F.R.S.

All media are considered, as far as their properties affect the propagation of electro-magnetic waves of frequencies as great as those of light, to consist of molecules, each comprising, in the simplest case, two oppositely charged atoms at a definite distance apart. In an electric field the positive atoms move to points of lower, and the negative atoms to points of higher potential. In doing so a molecule may be subjected to a rotational displacement, or its constituent atoms may be separated more widely from each other. Equations are determined giving the relation of the specific inductive capacity (the electric strain being steady) to the molecular displacements.

Maxwell's well-known equations are modified by adding to the total displacement current a term representing the convection current per unit volume. The existence of free ions is not considered capable of materially affecting the value of the refractive index for light waves. Subsidiary equations representing the conditions of the atomic vibrations are assumed, and the refractive index, μ, is finally given by the equation

$$\mu^2 = \mu_\infty^2 + \frac{c'\lambda_1^2}{\lambda^2 - \lambda_1^2} + \frac{c''\lambda_2^2}{\lambda^2 - \lambda_2^2}$$

μ_∞^2 represents the specific inductive capacity as previously determined.

Double refraction in a uniaxal crystal is explained by supposing the axes of the molecules to be arranged with their axes all parallel to one direction. Electric disturbances perpendicular to this direction will produce a molecular rotation, whilst those parallel to the molecular axes will produce a separation of the constituent atoms. Hence two different propagational velocities will follow. The connections of the above theory with Kerr's well-known experiments on the double refraction experienced by light when traversing a liquid dielectric subjected to electric stress, and the facts of pyro-electricity are obvious.

In order to account for the phenomena of the propagation of light in metals, a viscous term is added to the equation for the molecular vibrations. The square of the refractive index is hence derived as a complex quantity, the imaginary part being essentially positive. In those cases where the real part of the refractive index is a large negative number, it is pointed out that the velocity of propagation of light waves will be inversely proportional to the molecular viscosity (and therefore to the electrical resistance) of the metal, agreeing with Kundt's experimental relation.

Geological Society, April 6.—W. Whitaker, F.R.S., President, in the chair.—Prof. T. Rupert Jones exhibited and commented upon a series of large stone implements, sent to England by Mr. Sidney Ryan, from the tin-bearing gravels of the Embabaan in Swaziland (South Africa). Some implements lent by Mr. Nicol Brown, and analogous implements of rough quartzite, from Somaliland, lent by the Rev. R. A. Bullen, were also exhibited.—Prof. H. G. Seeley exhibited the humerus of a Plesiosaurian in which the substance of the bone was almost entirely replaced by opal. He explained that the fossil was from the opal mines of New South Wales.—On some Palæolithic implements from the plateau-gravels, and their evidence concerning "Eolithic" man, by W. Cunnington. Although at first inclined to believe that the chipping on the "Eoliths" of the plateau-gravels was the work of man, the author has been led to recant this opinion by the detailed study of specimens lent or given to him by Mr. B. Harrison. His reasons are mainly based on the facts that the chipping is of different dates, even upon the same specimen, and that it was produced after the specimens were embedded in the gravel. A further series of specimens, which, although not found actually *in situ* in the gravels, present undoubted evidence that they came from these, are considered by the author to be of Palæolithic type. One of them appeared to have gone through the following stages: first it was fashioned by man into a Palæolithic implement, then it was abraded, broken and chipped along one edge in the same fashion as the alleged "Eolithic" working; finally it was stained, marked with glacial striæ, and covered with a thin layer of white silica. This implement appears to prove that Palæolithic man lived on the Kentish plateau before or during the deposit of the plateau-gravels, and that the "Eolithic" chipping is not the work of man. A long discussion followed the reading of the paper, and was summed up by Dr. Gregory, who replied on behalf of the author. Dr. Gregory said he noticed in the discussion absolute unanimity on one point: no one denied that some of the specimens exhibited were worked by man, and that they were genuine plateau-gravel flints, which must have been flaked before the deposition of the gravels. Every speaker had therefore admitted that man lived in Kent before or during the deposition of part of the plateau-gravels. Thanks, therefore, to Mr. B. Harrison's magnificent perseverance and industry, man's age in Kent had been carried back one stage further. In the congratulations to Mr. Harrison on that achievement, no one would join more heartily than the author. But that admission did not affect the question of the specimens described as "Eoliths" or "rudes." Those who believed in these specimens still could not agree as to which are genuine and which are not. He thought the critical points of the paper had been ignored in the discussion: no attempt had been made to show that the implements were not Palæolithic, or that the "Eolithic" work was not later than the Palæolithic work. He quoted the opinions of Mr. Montgomery Bell and Mr. Harrison to show the identity of the working of the broken edge of the Palæolith with that of the Eoliths. It was only the "Eolithic" implements that the author had denied. The wide general importance of this question was the claim that the Kent plateau had been the home of a primitive pre-Palæolithic people, which, he held, the author's arguments conclusively disproved.—On the grouping of some divisions of Jurassic time, by S. S. Buckman. The author argues for an arrangement in the division of Jurassic time based upon the zoological phenomena of the Ammonite fauna.

PARIS

Academy of Sciences, April 12.—M. van Tieghem in the chair.—The President announced to the Academy the recent death of M. Aimé Girard, Member of the Section of Rural Economy (see p. 587).—Observations relative to the action of oxygen upon sulphide of carbon and to the chemical influence of light. Preliminary action determining the chemical changes, by M. Berthelot. In a mixture of air with the vapour of carbon disulphide exposed to diffused light no change was found to have occurred at the end of a year. Under the influence of direct sunlight, however, oxidation soon commences, but is by no means completed in a year. The effect produced is, therefore, not simply proportional to the luminous intensity, unlike the combination of hydrogen and chlorine, which commences in the most feeble diffused light and increases with the intensity.—On the absorption of oxygen by pyrogallate of potassium, by M. Berthelot. The principal defect of the common method of estimating oxygen consists in the simultaneous formation of small quantities of carbonic oxide. A number of experiments are described in which the influence of temperature, dilution, and the relative proportions of pyrogallol and potash upon the course of the reaction is ascertained. The author concludes that, in order that only negligible quantities of carbonic oxide may be produced, the absorption should be effected in presence of a large excess of potash and an amount of pyrogallol capable of absorbing four or five times the volume of oxygen likely to be present. From the products of the reaction an oxyquinone ($C_6H_4O_5$) may be extracted with ether, after acidification. This compound will be described later.—Flesh and starch compared with sugar, as regards nutritive value, in the case of a working subject, by M. Chauveau.—Addition to a preceding communication concerning the theory of quadratic forms, by M. de Jonquières.—Observations of Comet Perrine, made at the observatory of Algiers, by MM. Rambaud and F. Sy.—Expression of the derivatives of *theta* functions of two arguments by means of the squares of *theta* functions, by M. E. Jahnke.—On the systems of differential equations satisfied by quadruply periodic functions of the second species, by M. M. Krause.—On the equations of the theory of elasticity, by MM. Eugène and François Cosserat.—On the passage of electric waves from one conductor to another, by M. C. Gutton.—On the thermic properties of saturated vapours, by M. E. Mathias.—On a new apparatus for the raising of liquids, by M. G. Trouvé. The instrument combines the principles of the centrifugal pump and the water-spout. The liquid is given a gyratory or spiral motion by means of a revolving cone, from the larger end of which it is expelled through an orifice placed tangentially.—On the plane of magnetisation of magnetic pyrites, by M. Pierre Weiss. When a magnet is brought near a crystal of the mineral no attraction is observed when the plane of the hexagonal base is perpendicular to the lines of force, although it is very marked in any other position. Exact experiments are adduced to prove that magnetisation can only take place in one plane, the *magnetic plane.*—Rays emitted by compounds of uranium and of thorium, by Mme. Sklodowska Curie. A study of the influence of the rays emitted by various compounds of the two metals upon the conductivity of the air. A difference of potential of 100 volts was established between the two plates of a condenser (at a distance of 3 centimetres), one of which was covered with a uniform layer of the substance under examination. The current strength was measured by means of an electrometer. All the compounds of uranium and thorium are active; those of cerium, tantalum, and niobium but slightly so. Two minerals of uranium, viz. pitchblende (oxide of uranium) and chalcolite (phosphate of copper and uranyl), are much more active than uranium itself. It is to be observed that the most active elements, uranium and thorium, are those which have the highest atomic weights.—On a means of augmenting the intensity and the rapidity of action of the X-rays, by M. F. Garrigou. The rays are confined during their passage from the source to the fluorescent screen or photographic plate by a cylinder of glass or metal. They are thus concentrated, and produce the required effect in a shorter time.—On the combinations of pyridine and trimethylamine with formic and acetic acids, by M. G. André. The compounds of pyridine described in a previous communication have been further investigated, and their heats of formation determined. They were found to be completely dissociated on vaporisation. Similar compounds of trimethylamine have now been prepared, and found to be more stable than the corresponding pyridine derivatives.—Influence of wave movements upon the development of the larvæ of the frog, by M. Emile Yung. The eggs of batrachians are naturally deposited in the calm waters of marshes and lakes. The author has studied the effect of continual agitation on their development. The freshly fertilised eggs speedily die; but if the embryo be already formed before agitation commences, development continues, although the mortality is great. The surviving tadpoles are distinguished by horny formations in the buccal cavity and a remarkable development of the tail.

DIARY OF SOCIETIES.

THURSDAY, April 21.

Society of Arts (Indian Section), at 4.30.—Recent Railway Policy in India: Horace Bell.

Linnean Society, at 8.—On the Structure of *Dendroceros*: Prof. Douglas Campbell.—On the Pterylosis of the Owls: W. P. Pycraft.—On the Thymus and Thyroid of Marsupials: J. Johnston.

Institution of Electrical Engineers, at 8.—Cost of Generation and Distribution of Electrical Energy: R. Hammond. (Continuation of Discussion.)

Chemical Society, at 8.—The Carbohydrates of Barley Straw: C. F. Cross, E. J. Bevan, and Claud Smith.—Isomeric Bornylamines: Dr. M. O. Forster.—Some Derivatives of Benzophenone: Dr. F. E. Matthews.—Researches on Camphoric Acid: Dr. S. B. Schryver.—Ballot for Election of Fellows.

FRIDAY, April 22.

Royal Institution, at 9.—The Recent Eclipse: W. H. M. Christie, C.B., F.R.S.

Physical Society, at 5.—On a Method of Viewing Newton's Rings: Rev. T. C. Porter.

Institution of Civil Engineers, at 8.—New Cut Swing Bridge, Swansea: M. W. Henty.

SATURDAY, April 23.

Geologists' Association (Paddington Station, at 1.33).—Excursion to Reading. Director: J. H. Blake.

MONDAY, April 25.

Society of Arts, at 8.—Sources of Commercial India-rubber: Dr. D. Morris, C.M.G.

Royal Geographical Society, at 8.30.—Investigations in the Atlantic: H.S.H. the Prince of Monaco.

Institute of Actuaries, at 5.30.—On the Mortality in the British Navy and Army, as shown by the Official Reports: James J. McLauchlan.

TUESDAY, April 26.

Anthropological Institute, at 8.30.—Exhibition of Stone Implements from Swaziland, South Africa: Prof. T. Rupert Jones, F.R.S.—Exhibition of Stone Implements from South Africa: W. H. Penning.—A Study of African Crania: Frank C. Shrubsall.

Institution of Civil Engineers, at 8.—Annual General Meeting of Corporate Members.

Royal Horticultural Society, at 1.—Sweet-scented Leaves.

Royal Victoria Hall, at 8.30.—Motor Cars: Prof. D. S. Capper.

WEDNESDAY, April 27.

Society of Arts, at 8.—Photography and Colour Printing: Captain W. de W. Abney, C.B., F.R.S.

Royal Geographical Society, at 4.30.—The Possibility of Acclimatisation of Whites in Tropical Countries: Dr. Sambon.

Institution of Mechanical Engineers, at 7.30.—President's Address: S. W. Johnson.—First Report to the Gas-Engine Research Committee; Description of Apparatus and Methods, and Preliminary Results: Prof. Frederic W. Burstall.—Supplementary Paper and Adjourned Discussion.

THURSDAY, April 28.

Royal Society, at 4.30.

Institution of Electrical Engineers, at 8.

FRIDAY, April 29.

Royal Institution, at 9.—Magneto-Optic Rotation and its Explanation by a Gyrostatic Medium (with Experimental Illustrations): Prof. A. Gray, F.R.S.

Institution of Mechanical Engineers, at 7.30.—Steam Laundry Machinery: Sidney Tebbutt.

BOOKS, PAMPHLETS, and SERIALS RECEIVED.

Books.—Radiography and the "X" Rays: S. R. Bottone (Whittaker).—The Theory and Practice of Electrolytic Methods of Analysis: Dr. B. Neumann, translated by J. B. C. Kershaw (Whittaker).—Alternate Currents in Practice: translated from the French of Loppé and Bouquet by F. J. Moffett (Whittaker).—A Manual of Dental Metallurgy: E. A. Smith (Churchill).—A Manual of Dental Anatomy: C. S. Tomes, 5th edition (Churchill).—Musical Statics: J. Curwen, new edition, revised by T. F. Harris (Curwen).—A Student's Text-Book of Zoology: A. Sedgwick, Vol. 1 (Sonnenschein).

Pamphlets.—Tobacco Soils of the United States: M. Whitney (Washington).—Die Meteorologie der Sonne und das Wetter im Jahre 1888: Prof. K. W. Zenger (Prag).—Recent Laws against Injurious Insects in North America: L. O. Howard (Washington).

Serials.—Engineering Magazine, April (222 Strand).—Scribner's Magazine, April (Low).—Annales de Electrobiologie, &c., March (Paris, Alcan).—American Journal of Science, April (New Haven).—Record of Technical and Secondary Education, April (Macmillan).—Journal of the Institution of Electrical Engineers, April (Spon).—Terrestrial Magnetism, March (Cincinnati).—Journal of the Royal Statistical Society, March (Stanford).—Geographical Journal, April (Stanford).—Encyklopædie der Naturwissenschaften, Erste Abthg. 71, 72 Liefg., Dritte Abthg. 38 to 43 Liefg. (Breslau, Trewendt).—Zoologist, April (West).—Quarterly Journal of Microscopical Science, March (Churchill).—Journal of the Royal Horticultural Society, April (117 Victoria Street).—Journal of the Franklin Institute, April (Philadelphia).

BACTERIOLYSIS OF SEWAGE.

The Purification of Sewage and Water. By W. J. Dibdin, F.I.C., F.C.S., &c., late Chemist and Superintending Gas Examiner to the London County Council and the late Metropolitan Board of Works. Pp. xv + 248. Royal 8vo. (London: The Sanitary Publishing Company, Ltd., 1897.)

RECENTLY there has been an astonishing and sudden revival of interest in the question of the action of bacteria on dead organic matter. Pasteur's experiments on the production of disease by morbific germs were so brilliant that, for long, most workers at the subject kept very much in one groove; still there have always been those who, working very quietly, have been accumulating knowledge concerning the action of bacteria on dead material, and the part these organisms play in the process of disintegration of effete matter.

It has, however, long been known that in nature various processes of purification were undoubtedly intimately associated with the life-history of special groups of bacteria. Certain of these organisms, moreover, have been recognised as playing a most important part in bringing organic material into such condition that it may be readily oxidised; and in both France and England investigators have studied this action, especially in connection with the organisms that are associated with the process of nitrification. It is somewhat remarkable that notwithstanding these numerous experiments, and in spite of the fact that the importance of the part which bacteria play in bringing about natural decomposition, nitrification and similar chemical processes had been so early recognised, no systematic attempt on any large scale had until comparatively recently been made to carry out, artificially, what was recognised as being done on a most extensive scale in nature's laboratory. When once, however, a commencement had been made, the course of events was by no means slow, and many investigators soon turned their attention to the question of the disintegration of the organic matter in sewage, its oxidation and "mineralisation." Amongst these later workers, Mr. W. J. Dibdin has taken an important position, and, in connection with his office as chemist to the London County Council, carried on a series of experiments on the bacterial purification of sewage, which in future will certainly be looked upon as constituting one of the most important parts of the pioneer work on the subject that has been carried out in this country. As the outcome of this work, Mr. Dibdin has published in book form a collected series of articles on the purification of sewage and water; and for those who wish to obtain, in clear and concise form, an account of certain of the bacteriological processes involved in this purification, and who wish to have a summary of the chemical changes and results obtained, no better book is at present published. Now that the question is looked upon as of sufficient importance to demand the appointment of a Royal Commission, to assist the Local Government Board to gather information, some such book as that now before us comes very opportunely. It is fortunate, indeed, that the task of supplying such a book has been undertaken by one whose knowledge of the chemical processes involved is of a very wide and practical character, who has a fair knowledge of the essential details of bacteriology, but who, more important still, has had a very wide experience of the actual working of biological filters. The mass of material accumulated in this book does not at first sight appear, as the conclusions are usually so pithily put, and in such simple language, that the enormous amount of work and systematic observation on which they are founded is sometimes almost lost sight of.

In order to convey some idea of the scope of this work, it may be well to give a brief outline of the ground covered by Mr. Dibdin. After a couple of introductory chapters on the "history of putrefaction" and of the attempts that have, from time to time, been made to interfere with the process of putrefaction in sewage and in river-water, and after describing in some detail the various processes of disinfection, deodorisation, precipitation, and ordinary filtration, a short description of the now famous Massachusetts experiments is given. Then follows a very full account of a series of experiments carried out on the purification of London sewage in biological filter-beds at Barking, and the nature and amount of purification brought about in these filter-beds indicated, the measurement of the purification being taken (*a*) from the amount of oxygen absorbed; (*b*) from the amount of albuminoid ammonia got rid of; and (*c*) the increase in the quantity of nitrates. By passing the sewage intermittently through these filters, and by allowing them to rest and become aerated between the charges, it was found that a purification of from 41 to 85 per cent. was obtained; the whole of the organic matter in suspension was completely removed, and an effluent, in most cases fit to be sent into rivers, was obtained. This purification goes on at the rate of about three-quarters of a million gallons per acre of biological filter.

An installation at Sutton was worked on somewhat similar lines, but here the filtrate from one bacteria tank was passed through a second, in which the filtering material was of finer grain; by this means still better results were obtained, 80 per cent. of purification being about the average obtained. The final filtrates were free from all objectionable odour, and remained perfectly sweet on being kept in either open or closed vessels. At both Barking and Sutton the coarse suspended matter was strained out and buried, and the whole of the subsequent changes were supposed to be due to the action of aerobic organisms.

Mr. Dibdin then gives a description of a system which has been worked out by Scott-Moncrieff at Ashstead, and by Cameron at Exeter, who both use an anaerobic chamber in order to initiate an active preliminary breaking-down of the organic matter in the sewage before aerobic organisms are allowed to act upon it. They hold that in this way a more active disintegration of the organic matter is obtained; whilst, in addition, a process of peptonisation is carried on, with the result that a large quantity of the solid material is quickly thrown into solution, in which form it can be more readily acted upon by aerobic organisms. It is evident, from the description given and comments made by Mr. Dibdin, that he pins his faith to the aerobic method; though, from the evidence given, it seems probable that the author may in time come to modify his present position.

One of the most interesting sections in the book is that devoted to the description of the various methods by means of which Mr. Dibdin has obtained his results. The description of the micro-filter alone would well repay a perusal of the whole book; the ingenuity exhibited in this simple piece of apparatus marking out Mr. Dibdin as, if not a born, a well-trained experimenter. The methods of determining the amount of nitrates and of oxygen absorbed and dissolved, will appear to the ordinary reader to be considerably less complex and complicated than those usually recommended. This is due, in part, to the fact that some of the processes have undoubtedly been simplified; but it is due still more to the fact that, having worked so much with them, Mr. Dibdin is able to give clear and lucid descriptions of the essential parts of the process without overburdening them with details which, from a practical point of view, are of little importance.

A full description is given of the history of the purification of the Thames from the time that the reaches between Westminster and Waterloo Bridges had their banks covered with accumulations of offensive mud, deposited from water little better than sewage, to the time that fish made their way up the ditches which contained the effluent from the biological filter-tanks at Barking. The whole story is one of engineering, chemistry and bacteriology, set out in plain matter-of-fact form; but Hercules' task of cleansing the Augean stables was mere child's play to the problem that had to be attacked and solved between the years 1855 and 1895. The concluding chapters of the book are taken up with descriptions of some of the methods of ventilation and deodorisation of sewers; with a short account of filtration of potable water; a description of the character of the London water supply; with sections on the action of soft water upon lead; on the application of the biological process to the purification of waste water from private properties, asylums, schools, &c.; and, finally, one on the systematic examination of potable water. Appendices on methods of determining the amount of oxygen dissolved in water, and a detailed report to the London County Council on the experiments on the filtration of sewage effluent during the years 1892–95 complete the work.

Although the reader may not, and probably will not, always agree with Mr. Dibdin, the work on which the conclusions are based appears, in most cases, to be above criticism. The experiments are set out in such form that each one affords ample material on which to base an opinion; the statistics, observations and descriptions are of such a character that not only will they assist in this, but they also give evidence that Mr. Dibdin has made the subject thoroughly his own. His arguments are backed by facts and figures, all the results of careful investigation and of laborious work. The result is that we have a book of far more than ordinary interest, quite apart from the fact that the author has to deal with such interesting matter—a book that may with confidence be recommended to any who take an interest, however slight, in the subject of the bacterial treatment of sewage.

G. S. W.

SCIENCE AND ART OF BUILDING.

Modern Architecture. A book for architects and the public. By H. H. Statham, F.R.I.B.A., Editor of the *Builder*, &c. 8vo, pp. 275. (London: Chapman and Hall, 1897.)

Complete Perspective Course. Britannia Series. By J. Humphrey Spanton. 8vo, pp. 282. (London: Macmillan and Co., 1898.)

Notes on Carpentry and Joinery. By Thomas Jay Evans. 8vo, pp. 396. (London: Chapman and Hall, 1897.)

THE first of these three books suffers from the too prevalent custom of assigning a title to a book that conveys the idea of a greater scope and value than the contents can candidly be said to justify. In the preface the author fairly states the origin of the bulk of the book in a course of lectures delivered to a class of architectural students, not, it is true, previously published, but which, we venture to think, should have appeared in their primary form, possessing all the interest and actuality that such deliverances would have had; without being dressed up with a title that leads the reader to expect a more serious treatment of such an extensive subject as modern architecture.

There are undoubtedly many cultivated people to whom a clear account of modern architecture would be of the greatest interest, inquirers who from time to time, lighting upon some fine modern building, have been puzzled at the qualities which they have felt it to possess, but which are not, at the same time, those of ancient buildings with which the antiquarian leanings of most English people of taste might have made them familiar. Thus made dimly conscious of a new spirit in architecture, they have felt a novel ignorance of the aims and ideals of a modern art, of which very likely they had not been prepared to admit the existence.

A layman is heard to ask an architect, "What style do you call the Imperial Institute?" or "Who was the architect of that fine church of St. Augustine's, Kilburn, which I happened to see the other day?" and so on—questions that show how absolute an ignorance of the development of the architecture of the present day exists even in cultivated circles.

It is to this class, we imagine, that the author intends to appeal as the public mentioned in his title; but the circumstances of the origin of his book in lectures of the kind mentioned above, tells altogether against its usefulness in that respect. It contains a great deal of criticism that was sufficiently useful when directed to the students to whom the lectures were given, but which is out of place in a work addressed to a special class of the public outside.

Again, the author's position as editor of the *Builder* placed at his command a large supply of illustrations for these lectures from the plates of his own journal, which are here given in a much reduced, and consequently very poorly executed, form; but though the *Builder* retains the leading position amongst architectural papers, it cannot by any means be held to be a fully representative depository of the modern architecture even of England.

Very many of the best buildings never are illustrated at all, either because the architects do not care to publish, or else do not take the trouble to have elaborate drawings made solely for publication; while, on the other hand, there is a flood of second-rate work that is given to the world for obvious commercial reasons.

To rely upon the illustrated journals for a knowledge of modern work is as hopeless as the proceedings of an American critic, who in all good faith tried riding down the main streets of the metropolis on the top of an omnibus, in the expectation of forming an impression of the quality of modern architecture in London.

For a book with this title, the subjects illustrated are too incomplete for it to possess the scientific value that a comprehensive treatise would contain, and in the letterpress the same inadequacy prevails.

The best section is that on State and municipal architecture, the subject that seems to have the greatest interest for the author; but that on the highly important question of domestic work is only slightly treated, and that on church architecture is on lines which, we feel, would hardly be endorsed by those to whom the greatest progress in this branch, in modern times, has been due.

This is not the only section in which the tone of the work is unfortunate. The style in which it is written is hasty and journalistic, and we do not quite like the writer's method of making points by quoting what appears to have been said to him in private conversation, where views are apt to be expressed with a greater vivacity, not to say exaggeration, than the speaker would use in the more deliberate statement of writing.

The truth is, that there is no royal road or cheap handbook to a knowledge of modern architecture. The serious student must hunt up the buildings for himself, even if they are five miles from a railway station. The performances of a great architect are seldom known until his death, and perhaps not even then. The public have no knowledge of Nesfield, Devey, or Bentley, to take three names at random—none of whom, by the way, are mentioned in this book—except that, as regards the last, the writer seems to think that because the new Roman Catholic cathedral drawings have not been given to the *Builder*, that therefore "it is a design about which there is a great reluctance to give any definite informtion"; a very amusing remark in view of the fact that students interested in the matter have long ago bought copies of a publication in which the scale drawings and full particulars of this remarkable design have been given.

The book on perspective is one of those innumerable works that the modern craze for examination produces; it is designed to meet, as quoted on the title-page, the requirements of four examining bodies, and as the author is instructor to the Royal Naval cadets on the *Britannia*, he has the necessary teaching experience to make his work likely to be helpful to the unlucky souls condemned to these examinations. To the architect, for whom also the book is intended, perspective should present itself as an almost indispensable accomplishment, but one which it is also far more important to acquire through practice than theory. It is a rule that in perspective drawing, there are many ways of arriving at the desired result; and as a matter of fact, except in a few universal points, most draughtsmen have their own methods of reaching a given result. We never yet met a student who used the method given in Chapter xii. for making a sketch, but possibly it might be of service to a beginner. As specimens of drawings—a rather important, though neglected point—the illustrations leave something to be desired, and when architecture is given the design is also not the best selected. This, unfortunately however, is universal in many text-books. In Chapter xvi. the defects of perspective in photography are explained, and a useful method of correction is given, constituting a good feature of the work.

A diagram is also given of how to set a centrolinead, showing the increasing value attached to this useful instrument, which every student should be taught to handle.

The book is clearly arranged and well referenced, which is an important point for actual use, because whatever method of perspective setting-up the student uses, it is indispensable that he shou'd have it at his fingers' ends, so that he may not be hampered in devoting himself to an artistic result in his drawing; but, inasmuch as the memory is apt to be treacherous in such matters, facility of reference is an invaluable saving of time.

The volume on carpentry and joinery has also been written with the special object of preparing for examinations, and the present work refers to the first or preliminary course of the City and Guilds Institute, which is dealt with from a practical point of view; but a better title would be "mensuration, physics, plane and solid geometry, &c., as applied to carpentry, &c.," the bulk of the volume being taken up with these subjects. The book forms a good introduction to the subject, which we welcome as a method and an inducement for the British craftsman to study his craft in a more scientific manner than has been the case in the past. One or two points might be revised. Fig. 53 shows a pointed arch in stone which is scientifically wrong, as the meeting of the two arches should be a straight joint in order that each section may move independently without causing a fracture. Problem No. 90 could be described accurately instead of approximately by the "trammel" method, as indeed is explained in Problem 91. It is, perhaps, advisable to adhere only to exact methods for the workman, as he is liable to get muddled between two methods.

The exercises placed at the end of each chapter are well arranged, and should teach the workman to think for himself—a most important point.

Some misprints are, perhaps, inevitable where so many figures and letters are introduced, as 39° for 30° on p. 169. The chapter on isometric projection will be found very useful for explaining joints, &c., but the lettering to the diagrams is not as distinct as it might be, and could be improved by the author if a future edition is required. The chapters on setting out of doors and windows are well arranged, but the joints at the feet of principal rafter and tie-beam in Figs. 245, 246, 247 and 248, will not, it is hoped, be repeated in succeeding volumes. The chapters on the resolution of forces, mechanical contrivances, bending moments, &c., give a prominent place to the scientific part of the subject, a study which we can with confidence advise the craftsman to undertake. The chapter on the determination of stresses might be made somewhat clearer, having regard to the class of man for whom the book is intended, if the author would take the forces acting at any point always in the same order, and work round with the sun. Under "mechanical contrivances" no mention appears to be made of the screw, which is specially mentioned in the syllabus. We refer with regret to the fact that there is no index, which detracts materially from the value of a well-arranged book.

A GERMAN POPULAR ASTRONOMY.

Das Weltgebäude.—Eine gemeinverständliche Himmelskunde. Von Dr. M. Wilhelm Meyer. Mit 287 Abbildungen im Text, 10 Karten, und 31 Tafeln, im Farbendruck, Heliogravüre und Holzschnitt. (Leipzig und Wien: Bibliographisches Institut, 1898.)

IN a very handsome volume, well written, well printed, and well illustrated, Dr. Meyer has given us the main results of astronomical observation. We may congratulate both the author and his readers on the selection of the facts that has been made, and submitted to consideration. The arrangement of the material has evidently been the subject of much care and thought; but we cannot say that the final result commends itself entirely to our judgment. In a short preface, Dr. Meyer has intimated the general principles by which he has been guided in preparing his work. He has wished the reader to appreciate the grounds on which certain truths have been received, and not simply accept the assertions as an outcome of authoritative teaching. He admits that without mathematical symbols and analysis it may be difficult to offer direct proof in support of many statements; but by translating the results of mathematical deductions into the language of ordinary life, he thinks it possible to find an efficient substitute. It is not without a feeling of apprehension that one reads of threats of this kind. Efforts to reproduce mathematical results without the use of the necessary machinery generally prove wearisome to the mathematician, and unintelligible to the ordinary reader. But Dr. Meyer has not taken the matter too seriously, and even in his chapter on the Newtonian system avoids the perils of adhering too closely to his own principles.

The author has divided his book into two parts. The first is descriptive, and in this section his endeavour is to describe the whole universe as it may be seen with instruments particularly designed for special ends. The causes for these appearances, or the theories by which they may be explained, are reserved for the second part. Whether such an arrangement is satisfactory can only be decided by the student. To any one who approaches the book with a fair amount of astronomical knowledge, it appears cut in halves, without sufficient reason. As it is impossible within a limited space to describe each section separately, the author's method of treatment may be illustrated by referring to the description of the moon, given in the first section, immediately after describing, not at too great length, but adequately, the telescope and spectroscope and the processes of photography and photometry. We have first of all an account of the phases, for the detection of which no telescope is necessary, and for whose correct explanation but little ingenuity is required. The instrumental examination of the moon begins with the application of the spectroscope to the light, and the obvious deductions that follow its use are necessarily given. Having discussed the absence of an atmosphere, the effect of the sun's heat, &c., we get to the telescope and trace historically the cartography of the moon from Hevel to Schmidt. Finally, and also following chronological order, we reach the age of photography and the delineations of Weinek from the Lick negatives, many of which are reproduced. Particularly good and interesting are the comparisons instituted between portions of the lunar surface and certain districts on the earth, not by any means with the view of suggesting that the configurations have been produced by similar processes in each case, but as a convenient way of illustrating points of resemblance or emphasising points of difference. The Island of Corsica, the Colorado Cañon, the Yosemite Valley are all in turn discussed and made to illustrate some generic feature on the lunar surface. Altogether it is the best description of the moon we have read; and it is only when we come to remember what is omitted, that we have any sense of dissatisfaction. For instance, we find nothing about the distance of the moon, though the diameter is given. This is surely a departure from the rule to be purely descriptive, though the description gains immensely by it, since it enables comparisons to be drawn between similar features on the earth. Moreover, while the distance remains undetermined, the diameter must be taken on authority; and this is opposed to the fundamental canon of the preface. The geometry of eclipses has to be relegated to the second part, similarly with other phenomena depending upon the mass of the moon, such as the action of the tides or the effects of precession and nutation. The advantage of the arrangement does not seem evident, nor does it entirely fulfil the purpose for which it was designed, although each part is admirable in itself, but wanting in completeness and connection. The method pursued with the moon is continued throughout the solar system, though of course there is not always the same necessity to return to omitted portions. From the members of the solar system we pass to comets and meteors, and finally to the universe of the fixed stars. It goes without saying that these chapters are not only correct, but offer us the latest information drawn, as they are, from experts in their several branches of investigation. For the author, distrustful of his own knowledge, and remembering that the fact of to-day is liable to be displaced by the newer discovery of to-morrow, prudently placed his manuscript for correction in the hands of various authorities. Thus, Schiaparelli either describes or confirms the description of Mars, and Dr. Scheiner, of Potsdam, is responsible for the accuracy of the chapters on spectrum analysis. Dr. Ginzel, who has written so largely on ancient chronology, is willing to assist here in the discussion of eclipses, while Dr.

Seeliger, it is admitted, has by his suggestions and revision materially improved the chapter on gravity. If the section on telescopes had also been overlooked by a competent authority, perhaps Herschel's giant telescope would have been erected at Slough rather than at Bath; but wherever these eminent authorities have co-operated with the author, it is needless to say that we have an admirable result, correct in all important particulars.

As an example of the character of the second part of the work, entitled "Motion of the Celestial Bodies," we select the chapter on the figure of the earth. We make this selection the more readily because it affords an apt instance, not only of the successful treatment of a difficult subject, but illustrates the thoroughness attempted in German popular works. In English books of similar character the tendency is rather to adhere to subjects that lend themselves to pictorial illustrations of an interesting kind, or are capable of easy description, making no great demand upon the attention. Sir Robert Ball, it is true, has given us some charming chapters on the wanderings of the Pole, but writers who wield a less facile pen have generally left the subjects connected with geodetic measurements severely alone. In the Ipswich Lectures, Airy taught us how a base line was measured, and how triangulation was effected; but his example has not been generally followed. Newer methods and more sensational results have swallowed up the interest that once belonged to the science of exact measurement. But to Dr. Meyer the subject is not unwelcome. Adhering to his general plan of first showing the main principles underlying any process, without introducing needless niceties invented to provide against sources of error, he keeps the attention of the reader fixed on the main object of the investigation, without being lost in the intricacies of detail. In this way we see how latitude and longitude are determined, the gradual elimination of errors from the observations, and the regular approach to scientific accuracy. There is nothing wearisome in the account of triangulation, for it is brightened and relieved here and there by references to ancient history, to past expeditions, and the results of previous measurements. As might be anticipated, one does not find much reference to English work, that is not the object of the book; it is not the history of results, but the history of methods that is under consideration, and the countryman of Bessel can find all he wants in the writings of that astronomer and in the work of the "Europäischen Gradmessung." The deviations of the earth's figure from that of the surface of an ellipsoid of revolution, and the variation of gravity with the causes that contribute to it, are set out in great detail, showing that the author expects an audience of very considerable intelligence to follow him. This is a point that constitutes for us the real interest of the book, the evidence it affords of the existence of more general information than is usually to be met with in English readers. The author must have been aware of the eagerness of a large class to possess exact information, and has catered for it; but we cannot imagine that this book would enjoy a very large circulation in this country. Between the mathematical reader and the "man in the street" there is a great gulf fixed, which works of this character are calculated to bridge, but which at present find no great support from either description of reader. W. E. P.

OUR BOOK SHELF.

La Vie: Mode de Mouvement. Essai d'une Théorie Physique des Phénomènes Vitaux. Par E. Préaubert, Professeur an Lycée d'Angers, &c. Pp. 310. (Paris: Félix Alcan, 1897.)

WE can hardly suppose that M. Préaubert intends his remarkable speculation to be taken seriously. His contention is that life is essentially a mode of motion of the ether, and as such is closely allied with electricity and magnetism; finding, like these forces, its expression but not its origin in ponderable matter. It is, he maintains, in consequence of the failure to recognise the ether as the true seat of vital activity that all attempts to explain the phenomena of life on a purely chemical or physical basis have hitherto broken down. With the removal of "vitality" to the region of the ether, the material difficulties vanish; the connection between vitality and the other forces of the physical universe becomes declared, and biology resolves itself essentially into a mere question of mechanics. What then is the true distinction between life, on the one hand, and light, radiant heat and electricity on the other? The author answers that life is a series, not of vibrations, but of vortex-movements; his discovery, in fact, could hardly be better expressed than in the words of the puzzle-headed old Athenian in the "Clouds"—

Δῖνος βασιλεύει, τὸν Δί' ἐξεληλακώς.

It need, perhaps, scarcely be said that in support of his central position he has nothing to offer but a collection of assumptions and analogies, the former practically baseless, and the latter more or less loose. He seems, indeed, to forget in practice, though he recognises in words, the distinction between analogy and identity; and anything deserving the name of proof is conspicuously lacking. Space will not allow us to deal with his statements in detail; he commits himself to many that would be called in question by both physiologists and morphologists. We cannot, however, refrain from expressing our wonder that so many writers on evolution should virtually ignore the firm foundation laid by Darwin. So far as M. Préaubert's biological arguments are concerned, the theory of natural selection might almost as well be non-existent.

We doubted at the outset whether the author expected to be taken seriously. His closing passage contains what is in effect a *reductio ad absurdum* of his whole theory. F. A. D.

The Barometrical Determination of Heights. By F. J. B. Cordeiro, Surgeon U.S. Navy. Pp. 28. (London: E. and F. N. Spon, Ltd., 1898.)

IN the calculation of mountain heights by means of the mercurial barometer, accuracy depends on the efficiency of the formulæ employed. These formulæ are based necessarily on assumptions, as we do not know exactly the varying conditions of the air, and we therefore fail to take into account the exact data for the correct solution of the problem. As a rule, the formulæ are at most only approximations; but it is astonishing what good results may be obtained by paying strict attention to all details.

In this neatly bound little book we have an essay on this subject, which was originally entered in the Hodgkin Prize Competition under the auspices of the Smithsonian Institution, and was awarded honourable mention. The author has briefly brought up to date the problem of barometrical hypsometry discussed many years ago by Guyot. He points out where the old theories were lacking in accuracy, and furnishes a method which, besides being rigidly correct in theory, gives trustworthy results in practice. As an illustration of this, a series of observations is added. In the appendix the author describes a form of air barometer, the advantages of which over a mercurial barometer are compactness and portability, greater sensitiveness, greater simplicity in the calculations, and, lastly, greater cheapness.

All those who are interested in the measurement of heights by barometric methods should read these twenty-eight pages.

Laboratory Directions in General Biology. By Harriet Randolph, Ph.D., Demonstrator in Biology and Reader in Botany, Bryn Mawr College. (New York: H. Holt and Co., 1897.)

THIS booklet of 152 pages small octavo is a guide to a 142 hours' elementary laboratory course. The Fern and Earthworm are first dealt with, and then a series of animal and vegetable forms, in ascending order determined by convenience, the whole culminating in a small modicum of comparative embryology. Directions for manipulation are throughout rendered in italics. Of the making of books there is no end, but a pity 'tis that of the making of books such as this should be a beginning! The whole is but a set of rough laboratory notes of the time-table order, such as are everywhere used under prevailing custom and often destroyed when done with. They are of the kind justified only by the necessity for local adaptation of class work; but of this there is here no evidence, and we consequently regard their publication in book-form as superfluous.

The Freezing-Point, Boiling-Point and Conductivity Methods. By Harry C. Jones. Pp. vii + 64. (Easton, Pa.: Chemical Publishing Co., 1897.)

THIS little laboratory handbook is designed not merely as a guide to the manipulation of the methods of which it treats, but also to give the student an insight into the physical principles underlying them. The theoretical part is, however, in many places so compressed that, it is to be feared, the average student will hardly be able to follow it without some previous knowledge of the subject derived from other sources. The practical part is, on the other hand, very well done. It includes descriptions of Beckmann's and the author's apparatus for the determination of freezing-points of solutions, of the Beckmann boiling-point apparatus, as well as of the later forms devised by Hite and by the author, and of the Kohlrausch apparatus for the determination of the conductivity of solutions in the form described by Ostwald. The details of manipulation, on which the author's extensive practical experience of these methods entitles him to speak with some authority, should secure a hearty welcome for this book wherever laboratory instruction in physical chemistry is given.

Philip's Artistic Fruit Studies. By R. H. Wright. *Philip's Artistic Animal Studies.* By H. A. K. Dixon. (London: George Philip and Son, 1898.)

IN the lower standards of Elementary Schools the children are given various occupations, such as plaiting, crayon drawing, and macrami work, having for its object the training of the hand and eye. The collections of plant and animal studies now before us have been arranged for this purpose, and they will afford the young pupils for whom they are intended both pleasure and instruction. Each collection consists of a series of twelve original designs, simply coloured, and a series of twelve outline drawings for colouring with crayons or paints. From the fruit studies the children will learn a few details concerning common fruits; and the animal studies, containing coloured drawings of queen, male and neuter bees, the development of the frog, and similar subjects will be of value in interesting the pupils in natural history.

It would be an advantage to young pupils if the name of the object were in every case distinctly printed under both the outline and coloured drawings.

LETTER TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

"The Story of Gloucester."

MAY I ask the courtesy of a few words in further consideration of this, not in reply to your contributor, but as a plea for a little consideration to a few thoughts entertained by thousands on the other side of this controversy?

Let all the advocates of vaccination reflect that there is in the small-pox a disorder that affects the skin. That this serious damage to the skin is the real reason of the danger of the disorder; and that this damage to the skin makes any classification by skin marks a very unscientific and a very imperfect manner of dividing the cases. It is more serious than that. It makes classification by skin marks of vaccination almost certain to be erroneous. No certainty of correctness can be had, except in the mildest of the cases. In all the confluent cases, classification of the small-pox cases by skin marks will be in error with certainty. Therefore, as there has always been a most positive refusal to refer to the register of vaccinations, we have not the slightest reason for accepting the classification of hospital small-pox as correct. We have however, no other classification. We therefore must, perforce, accept for argument that classification. But we always do it with reserve.

These remarks are those which occur to us always in looking at the modern (post-vaccination) unvaccinated fatalities. If you are making a set of fatalities, which are enormously heavier than ever were recorded before Jenner began his vaccinations, then you are entitled to ask if there is in the fatality, taken as a whole, any justification for these unvaccinated fatalities, such as are now shown.

		Per cent.
Thus, Von Swieten's fatalities 150 years ago were under		2
The accepted fatality in this country before vaccination was		16
The Royal Commissioners give	Chester, 1774	16·8
,, ,, ,,	Ware, 1722	11·7
,, ,, ,,	Old Small-pox Hospital, 1746-63	25·3

This last is the very highest I have ever been able to find. And it is fully accounted for by the statement made in the report of the hospital in explanation of it, that "most of them were adults, often admitted after great irregularities, and some when their cure was despaired of." The hospital was small, and there was not a general admission of patients. Only free admission was allowed for those who were to have the inoculated small-pox. We have then to set against those fatalities, which are exhibited, for the most part, as showing how serious a loss of life was risked by the non-inoculated, the fatality of our own hospitals since the enforcement of vaccination. Thus—

	Per cent. died.
Metropolitan Hospital, 1870-72	18·6
Homerton Hospital, 1871-77	19·43
Metropolitan Hospitals, 1876	23
Same Hospitals for 1876-1880	17·3
Dublin, 1876-1880	21·7

In the recent years, as there has been a crowding of all the cases into hospitals, and a great deal of hospital extension—neyer known previously—we have a rather lower rate, as was to be expected; thus—

	Died per cent.
Fulham, 1879	16·2
Metropolitan Hospitals, 1884	15·8
Fulham, however, for 1885 was	24·3
And for Gloucester we have, 1895-96	21·9

There is here nothing to boast of in the fatalities of our compulsory vaccination period. There is never so low a fatality as that recorded by Von Swieten, or by Isaac Massey at Christ's Hospital, where only one child in some hundreds died (1722), and there is no avoiding the conclusion, that I can see, that if on the whole there is no lessened fatality, there is some error in the division, which makes one set appear to be vastly better off than the other. I have tested that in this way in the Gloucester cases, by asking if there was a single class free from fatality?

The answer is, of course, that there is not one. Government exacts multiple marks of vaccination, but in Gloucester it is clear that there was a better case for the single than for the multiple marks. Government exacts re-vaccination in the services, but here there is a large number of re-vaccinated cases, and twice Von Swieten's fatality in them.

Then, again, it is clear that the eruption has, as of old, everything to do with the fatality, and nothing can be clearer in the Gloucester cases. Unless, therefore, you have taken the precaution of giving reference to the register of vaccinations, you are in the fix of having almost certainly got wrong with your classification. Is there any test of this? There most certainly is. For in the variety of the disease, in which there is not so much damage to the skin as discoloration of it, where the poison is damaging the whole system, and internally more than externally, we have still the vaccination marks, if they are noted. I gave before the Commissioners all these cases that I had been able to trace in a large number of reports. And here is the fatality of these "malignant" cases.

	Per cent. died.
Vaccinated malignant cases	83·5
Unvaccinated cases	90
The first line divides thus—	
Vaccinated, no evidence	82
Doubtfully vaccinated	81
Indifferent vaccination marks	84
Good vaccination marks	85

It is very clear, therefore, that there is not the slightest influence in vaccination, good, bad, or indifferent, to abate the fatality of these cases. In some of the hospitals the whole of the vaccinated in this class died, without any recoveries. But that way of returning the cases is only followed occasionally, so that there is no possibility of taking all the hospital experience. There is however, no reason to suppose that it would show any different results. All these cases, with the almost unvarying total fatality, show that there is high time for a reference of every possible case returned as unvaccinated to the vaccination officer for his verification, and for information as to whether there had been the payment for successful vaccination. Till that is done, we have the right to say that there is not the slightest gain accruing from vaccination in the cures of the small-pox, and that there is all reason for declaring the present classification by skin marks in this eruptive disease unscientific and erroneous. ALEX. WHEELER.

Darlington, April 17.

[In deference to the wishes of Mr. Wheeler we print the enclosed letter, after which our columns must be closed to the subject unless something very important is brought forward. Of course, as Mr. Wheeler says, he has completely departed from the original controversy; and it is necessary to call attention to the fact that no amount of statistical jugglery, or reference to assumed historical data, can be held sufficient to refute the unquestioned fact that in Gloucester the unvaccinated children were attacked with small-pox and died in overwhelming disproportion to the vaccinated. Epidemics, as we know, cannot be compared with one another as regards their severity, but the incidence of attack in the same epidemic may always be taken as being fairly comparable throughout.—ED. NATURE.]

RÖNTGEN RAYS AND ORDINARY LIGHT.

ACCORDING to the theory of the Röntgen rays suggested by Sir G. Stokes,[1] and recently developed by Prof J. J. Thomson,[2] their origin is to be sought in impacts of the charged atoms constituting the kathode-stream, whereby pulses of disturbance are generated in the ether. This theory has certainly much to recommend it; but I cannot see that it carries with it some of the consequences which have been deduced as to the distinction between Röntgen rays and ordinary luminous and non-luminous radiation. The conclusion of the authors above mentioned,[3] "that the Röntgen rays are not waves of very short wave-length, but impulses," surprises me. From the fact of their being highly condensed impulses, I should conclude on the contrary that they *are* waves of short wave-length. If short waves are inadmissible, longer waves are still more inadmissible. What then becomes of Fourier's theorem and its assertion that *any* disturbance may be analysed into regular waves?

Is it contended that previous to resolution (whether merely theoretical, or practically effected by the spectroscope) the vibrations of ordinary (*e.g.* white) light are regular, and thus distinguished from disturbances made up of impulses? This view was certainly supported in the past by high authorities, but it has been shown to be untenable by Gouy,[1] Schuster,[2] and the present writer.[3] A curve representative of white light, if it were drawn upon paper, would show no sequences of similar waves.

In the second of the papers referred to, I endeavoured to show in detail that white light might be supposed to have the very constitution now ascribed to the Röntgen radiation, except that of course the impulses would have to be less condensed. The peculiar behaviour of the Röntgen radiation with respect to diffraction and refraction would thus be attributable merely to the extreme shortness of the waves composing it. RAYLEIGH.

April 18.

THE BAKERIAN LECTURE.[4]

THE purpose of the lecture was to show that certain metals and certain organic bodies can act on a photographic plate in such a manner that, on treating it exactly as if it had been acted on by light, a picture is developed. When carrying on some experiments with photographic plates, a piece of perforated zinc was found not to act as a screen and give a picture of the holes, but to give a picture of the metallic part; and further, it was found that a bright piece of zinc, when coated with copal varnish, with the object of stopping any emanation of vapour from it, became more, not less, active; these were the accidental observations which gave rise to the present investigation. With regard to the action of the organic bodies: their activity is greater than that of the metals, and the experiments with them are more easily carried out, hence it was advisable to investigate to a considerable extent their action before undertaking the more intricate and, probably, more important action of the metals.

Printing ink is one of the many substances which will, both when in contact and when at a distance, act on a photographic plate, and it was shown that remarkably clear pictures can be obtained of ordinary printing and of lithographic pictures. Printing ink varies in composition, and if the ordinary newspaper's, for instance, be used, the density of the pictures obtained will vary considerably. The varnish known as picture copal is also an active substance producing a dark picture. The active constituent of the printing ink was proved to be boiled oil, and in the varnish to be turpentine; and these bodies alone can be used in place of the more complicated substance above named. If then boiled or drying oil was active, it was natural to try linseed oil in its ordinary state, and this proved also to be active; different specimens, however, of so-called pure oil vary very considerably in the amount of their activity. Passing from linseed oil to other vegetable oils, they were found also to be active, but apparently none so active as the linseed oil. Then, with regard to turpentine, a body belonging to a very different class of organic substances, it was found that bodies analogous to it—all the terpines, for instance—were exceedingly active bodies; and it is interesting to note that with some of them an effect on the sensitive plate, analogous to what photographers term reversal or solarisation, is readily produced. With excessive action, a white in place of a black picture is obtained, but with modified action an ordinary dark picture is formed. All the fragrant essential oils are active bodies, and all contain as an ingredient one or more of the terpines. Now a characteristic property common to all the above-named bodies, and to others which produce similar effects on a photographic plate, is that they are reducing or oxygen absorbing bodies; consequently it is probable that it is to this property that they owe their power of acting on a photographic plate. Bodies such as alcohol, ether, esters, benzene, petroleum spirit, &c., exert no such action. Linseed oil is the most active of the vegetable oils, and has the greatest oxygen-absorbing power, olive oil the least, and it can produce little or no action on a photographic plate. An interesting test as to certain impurities in inactive bodies, for instance in alcohol and in ether, can be founded on these reactions. Ordinary commercial samples of these bodies, when placed in a dish with a photographic plate above them, yield a picture; but on carefully applying the ordinary processes for purifying these bodies, the pictures produced become fainter and fainter, and at last entirely disappear, so that not only the process of purification can be rendered visible step by step, but its completion be proved. One remarkably interesting character of these actions is, that they can take place through thin layers of certain solid substances; for instance, through gelatin, celluloid, collodion, gutta-percha tissue, gold-beater's skin, tracing-paper, &c., and naturally the action permeates paper and other strongly porous bodies. In so doing it gives on the sensitive plate a picture of the structure of the body. That the passing through a medium such as gelatin is not one of mere absorption on one side and evaporation on the other, is proved by the formation, after having passed through the medium, of a clear picture of the surface, say hardened copal varnish, from which the action arose; and even when more than a single layer of gelatin is interposed between the active body and the plate, still a clear picture is produced. On the other hand, bodies such as glass, mica, and selenite are perfectly opaque to the action, and gum arabic and paraffin in thin layers do not allow the action to pass through. Experiments were described in the lecture to show that it is a vapour given off by the active bodies which is the immediate cause of the action on the photographic plate, not a fluorescence emanating from the active body. A card, for instance, painted with drying oil or copal varnish, smaller than the photographic plate, and placed below a sensitive plate with the film upwards, produces an action round the edge of the plate, which creeps slowly and unevenly towards the centre. An arrangement was also described with a series of mica plates, overlapping one another so as to cut off all direct view of the active body from the sensitive plate, but so arranged as to allow a space between each layer, so that a vapour could work its way from the source of the action to the sensitive film. Such an arrangement enclosed in a box produced a definite picture.

[4] Delivered before the Royal Society, March 24, by Dr. W. J. Russell, V.P.R S.

It was naturally to be expected that an inactive substance, such, for instance, as a piece of Bristol board, could be made active by placing it in contact with hardened drying oil or copal varnish, or simply by placing it over linseed oil or turpentine; and the Bristol board, although no change in the surface is visible, will now produce a definite picture. High temperatures cannot, of course, be used with photographic plates. Many experiments have, however, been made at 55° C., and the action at this temperature as compared to that at ordinary temperatures show that a very great increase of activity takes place with the increase of temperature.

Experiments similar to those which have been indicated as having been made with organic bodies, have also been made with the different active metals, and similar results obtained. Zinc is, perhaps, the most convenient metal to experiment with. That it possesses this property of acting on a photographic plate was first published by M. Colson, but unknown to the lecturer until after his first set of experiments were made. The following is a list of the metals which have been found to be most active, and they are arranged approximately in the order of their activity. Magnesium, cadmium, zinc, nickel, aluminium, lead, bismuth; then follows cobalt, tin, antimony, which are decidedly less active than the foregoing ones; and there are others which with very long exposure show some amount of activity. Again certain alloys, such as pewter and fusible metal, are active bodies, whereas ordinary brass and german silver are not so. Increase the amount of zinc in brass, and it becomes an active alloy. The conditions under which this change occurs are being investigated. From the first experiments which were made it was concluded that mercury was an exceedingly active metal, but it has since been proved that it is entirely inactive, and that the action previously obtained was due to the metal being alloyed with a trace of zinc. That an exceedingly small amount of zinc is capable of effecting this change in mercury, is an interesting and important fact. This action can also be utilised as a test for the absence both of zinc and lead (for this metal acts in the same way as zinc) in a specimen of mercury, and pictures were shown which exhibited the effect of several of the ordinary purifying processes on impure mercury.

In order to show that the action exerted by the metals is due to a vapour, as before stated, experiments similar to those made with the organic bodies, and other ones described in the lecture, have been carried out. For a metal surface to be active it must be bright; a piece of dull zinc, for instance, exerts no action on the photographic plate, but rub it with coarse sand or emery paper, and you get a surface which will give an exact picture of every line that is visible on the plate, and even when a sheet of gelatin or celluloid is interposed, still a picture of the metal surface is formed. As a further confirmation of the view that a vapour is given off by the metal, it was shown that a slow current of air passed over bright zinc and allowed to impinge on a photographic plate, acted on it and produced a picture. Interesting pictures of opaque bodies are readily produced by placing a plate of polished zinc behind them, and in this way, for instance, the structure of different papers and the water-marks they bear, the form of skeleton-leaves, &c., are obtained as pictures. The opacity which certain solutions give to paper, and the transparency which others communicate to it, is of much interest, and further experiments are being made on this branch of the subject.

Another curious action was mentioned, which is that zinc and other metals have the power of making certain inactive liquids active. If, for instance, alcohol or ether or acetic ether be digested for four days with bright zinc, it will become active and capable of producing a picture; filtration and even distillation does not restore the inactivity of the solution.

It appears then that many substances, both organic and metallic, are able to act on a sensitive photographic plate, and that exceedingly small quantities of these active bodies are sufficient to produce the effect. A piece of board laid on a sensitive plate will give a good picture of its structure, and even thin dry board 30 to 100 years old can be made to give its likeness. Dry cinnamon and many other bodies act in the same way. Other experiments were described showing how an accumulation of the active vapour from zinc could be demonstrated, and, further, how the vapour was reflected from the sides of a glass or paraffin tube, but absorbed by a paper one. The foregoing outline shows some of the principal points described in the lecture. The subject is a far extending one, and it is more important at the present time to obtain accurate data than to suggest theories; many other interesting points have, in fact, already been determined. The lecturer noted that the above experiments had been made in the Davy-Faraday Laboratory.

ANDRÉE'S BALLOON EXPEDITION.[1]

ALTHOUGH the fact is not stated, this is a translation, and a singularly literal one, of the French original. It is to be regretted that obvious printer's errors or slips of the pen were not corrected; for example, "1892" for "1882" on p. 14, "south" for "north" on p. 280, and the somewhat serious misstatement of Andrée's last message on p. 10, which is the least excusable, as a facsimile with correct translation attached is given on p. 306. On p. 168 the translator computes 5000 cubic metres at 17,658 cubic feet instead of 176,580. A somewhat infelicitous if not unintelligible paraphrase of marking a pigeon's feathers with an india-rubber stamp, is fixing on labels by the aid of india-rubber wafers (p. 233). It must be stated, on the other hand, that the English edition is much better printed than the French, especially as regards the extremely interesting plates, and that it contains an effective coloured frontispiece showing the departure of the balloon.

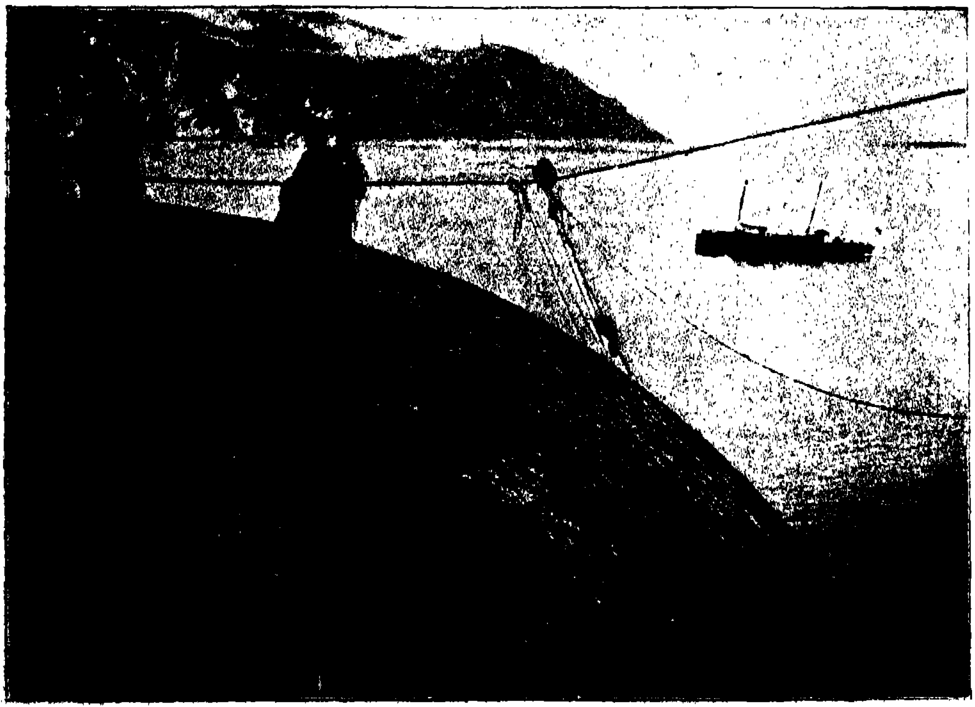

Fig. 1.—The top of the balloon, showing the joinings of the pieces.

The narrative is in two parts. The first, by M. Lachambre, describes the balloon and the process of its manufacture, the transport of the material to Dane's Island in 1896, the erection of a shed, the inflation of the balloon, the long waiting for a favourable wind, the deflation and return. The second part, by M. Machuron, the nephew and partner of M. Lachambre, describes the transport of the enlarged balloon to Dane's Island in 1897, the repair of the shed, re-inflation, and the casting off on July 11. Both authors describe their own work clearly and well. They have nothing to say as to Andrée's plans, his theory of circumpolar prevailing winds, or his probable fate. But the technicalities of balloon construction, and the dexterous manipulations of the delicate fabric as it was prepared far from workshops or extraneous help, are lightened by the ingenuous impressions of the two intelligent Parisians suddenly transported into so strange a world.

The balloon *Ornen* was constructed as a sphere sixty-six feet in diameter with a conical appendage. It was furnished with two lateral valves for releasing the imprisoned gas at will, a large automatic valve to let the gas escape whenever the internal pressure exceeded a certain limit, and a rending flap intended to be used to prevent bumping on finally alighting, and so constructed that a rope attached to a small grapnel, on being thrown to the ground, would tear a great rent in the side of the balloon, deflating it instantaneously. The cubic contents were 160,000 cubic feet; but this was increased for the second attempt to 176,000 cubic feet. The material used was pongee silk of double, triple, or quadruple thickness, according to the part of the balloon and the strain to which it would be subjected. The silk was prepared in pieces of about 18 inches in width, and the balloon was made up of horizontal zones, the joints of each successive zone being alternate, as in brickwork. When completed the whole was thoroughly and repeatedly varnished inside and outside. While both Andrée and the manufacturers were confident of the gas-retaining power of such a construction, we understand that some experienced aeronauts view it with great suspicion, and greatly prefer the old system of vertical gores. The wicker car was fitted up with marvellous ingenuity, and attached by a ring to a cord net thrown over the balloon. A cap of varnished silk on the top of the balloon protected the net from snow. Andrée's plan was to keep the balloon within a few hundred feet of the ground by the use of heavy guide-ropes dragging over the ice or through the sea, a device which serves as an automatic regulator of height.

---

[1] "Andrée and his Balloon." By Henri Lachambre and Alexis Machuron. With coloured frontispiece and 44 full-page illustrations from photographs. Pp. 306. (Westminster: Archibald Constable and Co., 1898.)

The erection of the balloon-shed, gas-generators, and the inflation of the balloon in the far north of Spitsbergen formed a very neat piece of engineering, of which the Paris firm and their Swedish colleagues may well be proud. We may recall the facts of the departure. The balloon glided through the demolished north side of its shed at 2.30 p.m. on Sunday, July 11, 1897, and slowly swept northwards across the bay and over the low hills on the horizon. The last authentic pigeon-message received runs: "July 13. 12.30 p.m. 82° 2′ N. lat., 15° 5′ E. long. Good journey E. 10° S. All well on board. This is the third pigeon-post.—Andrée."

Beyond this all is conjecture; but before adopting pessimistic views as to the fate of Andrée, Strindberg and Fraenkel, we should remember how few believed in July 1896 that the *Fram* would ever return. There is still hope for the crew of the *Ornen*.

Hugh Robert Mill.

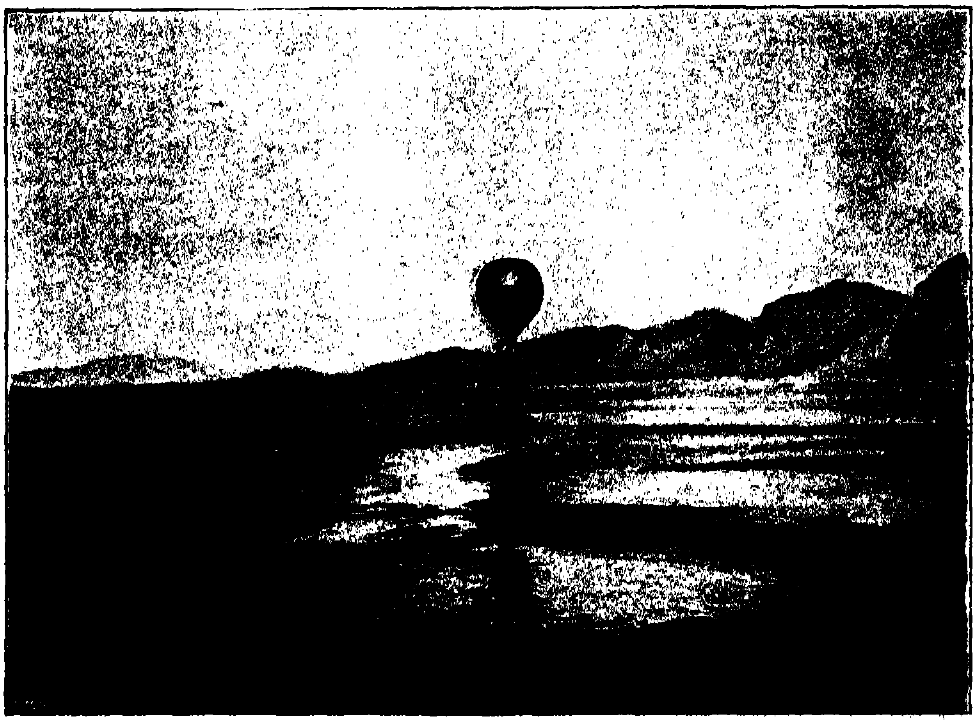

Fig. 2.—The balloon on its departure, showing guide-ropes.

THE BENEKE PRIZES.

THE Philosophical Faculty of the Georg-Augusts-University of Göttingen has just published the following information concerning the Beneke prizes for the years 1897 and 1901. On March 11, 1898, the birthday of Carl Gustav Beneke the founder of this prize, it was announced that no communication had been sent in for the prize competition for the year 1897. At the same time the Philosophical Faculty set the following problem for the year 1901.

The principle of continuity, or more exactly the representation by functions which can be indefinitely differentiated, has for a long time been regarded as a general valid foundation for the mathematical treatment of natural phenomena. Such a groundwork as this was quite naturally introduced by the discoverers of the differential and integral calculus. More recently, however, the progress of mathematical investigation has shown generally that this is founded on a great number of implicit suppositions to which we, in consequence of the inaccuracies of our sensitive perceptions, are not bound. Further, the assumption of the molecular constitution of matter is from the first in contradiction with well-known laws.

The Faculty wishes to receive a work of real scientific interest in which such questions will be treated in a general intelligent way, and in which a minute examination will be made regarding the admissibilty in relation to the appropriateness of the usual mode of representation. Communications may be mathematically or philosophically and psychologically inclined, and historical studies are desired but not demanded

Papers competing for this prize must be written in a modern language, and will be received by the Dekan of the Philosophical Faculty up to August 31, 1900. A motto should be written on the title-page of the work and on the outside of a sealed letter which must accompany it, containing the name, profession, and address of the sender. In no other way can the name of the author be communicated. It is further requested that the address of the sender should be also written on the title-page, in case the prize should not be awarded to it. The first prize amounts to 3400 marks, and the second to 680 marks.

The prizes will be awarded on March 11, 1901, at a meeting of the Philosophical Faculty in Göttingen. The communications to which prizes are awarded remain the property of the authors. The prize problems, for which the competitive papers must be sent in by August 31, 1898, and August 31, 1899, will be found given in the *Königlichen Gesellschaft der Wissenschaften Geschäftl. Mittheilungen*, 1896, S. 69, 1897, Heft. 1, S. 26.

NOTES.

THE Committee of Administration of the Paris International Exhibition of 1900 have adopted a scheme of arrangement of the exhibits according to the nature of the objects, instead of by nationalities. The exhibits will be arranged in groups, containing between them 120 classes. The subjects of the groups are: education and teaching, literature, science and art, instruments and processes; machinery and mechanical processes; civil engineering, construction, means of transport; agriculture, horticulture, arboriculture, forestry, sport, &c.; alimentary products; mines and metallurgy; decoration and furniture of public and private buildings; yarns, fabrics, clothing; industrial chemistry; miscellaneous industries; social economy, hygiene, public charities; colonisation; naval and military.

PRINCE ALBERT OF MONACO gave an account of his investigations in the Atlantic at the meeting of the Royal Geographical Society on Monday. From 1885 to 1889 Prince Albert made some long cruises in the *Hirondelle*, a little sailing schooner of 200 tons, which took him as far as the American coasts, and he explored depths as great as 1600 fathoms without help of any power greater than the arms of his fourteen sailors. The *Hirondelle* being shattered by storms, he built a stronger steam-vessel, the *Princess Alice*, 560 tons, to carry on the same research with better appliances. The work of this second period opened up to him fields of labour altogether beyond his reach without the aid of a still larger and more powerful vessel, so he commissioned Messrs. Laird, of Liverpool, to build him another *Princess Alice*, which is expected to set out on her first voyage in a few weeks. After giving the results of the more important of his observations with respect to currents, depth and pressure, temperature, salinity, light, and ocean deposits, Prince Albert proceeded to treat of the organic life inhabiting the waters of the open ocean, and described the principal apparatus employed by him for biological investigations.

MR. W. H. PREECE, C.B., F.R.S., was elected president of the Institution of Civil Engineers at the annual general meeting held on Tuesday.

MR. J. J. H. TEALL, F.R.S., has been elected into the Athenæum Club, under the rule which empowers the annual election of nine persons "of distinguished eminence in science, literature, the arts, or for public services."

THE Royal Photographic Society's International Exhibition was opened by the Prince of Wales at the Crystal Palace on Monday. A large number of interesting photographs, many of them illustrating scientific applications of photography, are included among the exhibits.

THE annual reception and exhibit of recent progress in science of the New York Academy of Sciences was held on April 13 and 14. Though not so large as former exhibitions, it was characterised by the president of the Academy, Prof. Henry F. Osborn, as the most complete and diversified of any, representing nearly all the leading educational institutions of the United States, and containing exhibits from very many of the States and many foreign countries. Addresses were delivered by the recording secretary, Prof. Richard E. Dodge, President Osborn, Prof. George E. Hale, of the Yerkes Observatory, on "The Function of Large Telescopes," Mr. Morris K. Jesup, president of the Museum, and Mr. Charles E. Tripler, who exhibited liquid air obtained by his apparatus. Among the objects included in the exhibition, the fine array of photographs of stars and star spectra was noticeable. In the department of photography some excellent colour photographs were shown, including a demonstration of colour photographs by the Joly process, shown by the Joly-Zambra Company.—In electricity, apparatus was exhibited for the transmission of signals without intervening wires. The feature of the palæontological exhibition was the caudal vertebræ and limb bones of the gigantic Dinosaur Camarasaurus, the largest land animal that ever lived. The bones exhibited were the largest yet found, and were recently exhumed. Several new kinds of apparatus were shown in the physics section. Specially important, in an economic sense, was the stremmatograph, an instrument to measure compression and extension of rails of a railroad during the passing of trains, exhibited by Mr. P. H. Dudley.—The geological exhibit contained many interesting features; including specimens brought back from the excursion of geologists after the geological congress in Russia last year, some of the latest maps of the U.S. Geological Survey, a model of the Franklin furnace zinc ore bed from New Jersey, gold-bearing conglomerates from the so-called "banket" reefs near Johannesburg, South Africa. Specimens of compressed marble were shown, which had been subjected to the pressure of 100 tons to the square inch without rupture or destruction of cohesion.—Mr. H. E. Crampton, jun., exhibited some fine specimens of fused or compound pupæ and compound adult moths. His recent products include some very perfect tandem moths with two full sets of wings; also moths which have the head of one grafted upon the back of another. The exhibition of ethnology included results of the Jesup North Pacific exploring expedition and collections of the Huichol Indians of Mexico. The exhibits generally were designed to show the progress made during the year. The department of philology, however, having only been added to the exhibition this year, took a wider range.

IT is announced in *Science* that at the recent annual meeting of the New York Academy of Sciences the following elections as Honorary and Corresponding Members were made: *Honorary*—Prof. Arthur Auwers, Astronomer, Berlin; Prof. W. K. Brooks, Biologist, Baltimore; Prof. David Gill, Astronomer, Cape Town; Dr. George W. Hill, Mathematician, Nyack; Prof. E. Ray Lankester, Zoologist, Oxford; Dr. Fridjof Nansen, Explorer, Kristiania; Prof. Albrecht Penck, Geographer, Vienna; Prof. Wilhelm Pfeffer, Botanist, Leipzic; Prof. Hans Reusch, Geologist, Kristiania; Prof. Rudolph Virchow, Biologist, Berlin; Prof. Karl von Zittel, Palæontologist, Munich. *Corresponding*—Prof. F. D. Adams, Geologist, Montreal; Prof. I. B. Balfour, Botanist, Edinburgh; Prof. George Baur, Palæontologist, Chicago; Prof. William Carruthers, Botanist, London; Prof. T. C. Chamberlin, Geologist, Chicago; Prof. Wm. M. Davis, Geographer, Cambridge; Prof. Adrien Franchet, Botanist, Paris; Prof. George E. Hale, Astronomer, Chicago; Prof. J. P. Iddings, Geologist, Chicago; Prof. Charles S. Minot, Biologist, Boston; Prof. George Murray, Botanist, London; Prof. William B. Scott, Geologist, Princeton; Mr. Charles D. Walcott, Geologist, Washington; Prof. Charles O. Whitman, Biologist, Chicago; Prof. Henry S. Williams, Palæontologist, New Haven.

A VERY elaborate series of experiments on the tractive resistance of express passenger trains running on the Northern of France Railway shows (says *Engineering*) that the engine and tender resistances amount to about half the total. The trains on which the experiments were made weighed, on the average, 160 tons, exclusive of the engine and tender, which weighed 85 tons more.

THE Royal Agricultural Society offers, in connection with the meeting at Maidstone next year, a prize of 50*l.* for the best machinery for washing hops with liquid insecticides, the machine in question being worked by horse or mechanical power. Full particulars of the regulations governing the proposed competitive trials can be obtained on application to the Secretary, 13 Hanover Square, London, W.

Prof. James E. Keeler, of the Allegheny Observatory, has definitely accepted the post of director of the Lick Observatory, and will go to Mount Hamilton next month. It will be remembered that he offered to remain at the Allegheny Observatory if 200,000 dollars could be collected to erect and endow a new observatory. The subscriptions did not reach this amount in the two weeks allowed, but 150,000 dollars was subscribed, so that a new observatory will be built.

A new coherer for use in connection with telegraphy without intervening wires has been invented by Dr. H. Rupp, of Stuttgart. Instead of using an electro-magnetic tapper to tap the coherer tube, and so loosen the iron filings in it, Dr. Rupp has devised a simple contrivance for making the coherer rotate round the axis of the leading-in wires. It is stated that the Morse signals obtained with this rotating coherer are much more distinct than those given by the tapping arrangement.

Dr. Henry Marshall, a distinguished member of the medical profession, died on Sunday at Clifton, Bristol. Dr. Marshall received his medical education at Edinburgh; and in 1854, was dresser and afterwards assistant under Lord Lister, whom he succeeded as house surgeon. Whilst in Edinburgh he held the presidency of the Royal Medical Society there. When the British Medical Association met at Bristol in 1863 Dr. Marshall acted as secretary, and he was president of the Bristol branch when in 1877 the Association met at Bath.

We have just received, with regret, the announcement of the death, on March 24, of Mr. Alfred U. Allen, of Bath, at the age of sixty-four. Mr. Allen's name will be long remembered by microscopists as the secretary of the Postal Microscopical Society, which came into existence about twenty-five years ago largely through his exertions. It is only a few months since we announced that Mr. Allen had found it necessary to discontinue the *Journal of Microscopy and Natural Science*, which he edited since 1882. In addition to this, Mr. Allen issued a monthly journal, under the title of *The Scientific Enquirer*, during the years 1886–88.

Col. Sir Vivian D. Majendie, K.C.B., the chief inspector of explosives to the Home Office, died suddenly on Sunday. He was the author of the Official Guide-book to the Explosives Act of 1875, and several other professional works. In his official capacity he was responsible not only for the periodical inspection of the various gunpowder and kindred manufactories scattered throughout the country, and for the investigation of the circumstances attending the accidents that occur in them from time to time, but also had to examine very many of the bombs and infernal machines that fell into the hands of the police, or were left for felonious purposes in public places. He was also concerned with drawing up regulations for the storage of inflammable liquids such as petroleum, and it is not very long since he returned from a tour in America undertaken to study the methods of storage and transport in operation there.

Zoology has lost an able student and a promising investigator by the death, at the age of twenty-six years, of Mr. B. B. Griffin, announced in *Science*. Mr. Griffin took part in the zoological expeditions to the north-west coast of America, sent out by Columbia University in 1896 and 1897. He was the author, wholly or in part, of several papers relating to the fauna of that region, one of which, dealing with the nemertines of Puget Sound and describing a number of species new to science, had been sent to press immediately before his last illness. His principal work lay, however, in the field of cellular biology, and a brief but important paper by him on the fertilisation of the egg in *Thalassema*, published in the *Transactions* of the New York Academy of Sciences for 1895–6, had attracted considerable attention, both in the United States and elsewhere. A more extended paper along the same lines, bringing forward new and important evidence on the nature of fertilisation, the history of the centrosome, the phenomena of chromatin-reduction and other vexed problems of cytology, was practically ready for the printer at the time of his death.

We regret to record the death of the distinguished geologist M. Jules Marcou. He was born at Salins in the Department of Jura in France, in 1824. In 1848 he joined Agassiz at Boston, in the United States, and spent two years in studying the geology of various portions of North America. In 1853 he published a Geological Map of the United States, and the British Provinces of North America. For a period of about twelve years M. Marcou appears to have spent much of his time alternately in Europe and America. In 1855 he became professor of geology and palæontology at the Polytechnic School of Zürich, but relinquished this office on his return to the United States in 1860. In 1861 he published his well-known Geological Map of the World, of which a second edition was issued in 1875. In addition to his works on the geology of North America, he published many papers on the European secondary rocks, and was specially interested in the Jura-Cretaceous formations. Some of his articles were of a controversial nature. In 1879 he was elected a Foreign Member of the Geological Society of London. He died on April 18, at Cambridge, Massachusetts, aged seventy-four.

It is with much regret that we record the death of Dr. John Shearson Hyland, F.G.S., at the early age of thirty-two. The second son of Captain P. Hyland, of Great Crosby, he was educated at the Merchant Taylors' School, at University College, Liverpool, and subsequently at Leipzig. At the University of Leipzig he studied mineralogy and petrology under Dr. Zirkel, and took the degree of Ph.D., his thesis being entitled "Ueber die Gesteine des Kilimandscharo und dessen Umgebung," and published in 1888. In the same year he joined the staff of the Geological Survey, and was for three years occupied in the Irish branch in investigations on the eruptive rocks of the country. During this period he published several papers on petrological subjects, and gave great promise of a brilliant career. Being of an active, enterprising nature, he relinquished the work of the microscope, and throwing up his post on the Geological Survey, took to the more practical work of reporting on mineral resources in the United States, subsequently in British Central Africa, and finally on the treacherous west coast of Africa, where he died at Elmina on April 19.

The death is announced of Dr. J. G. N. Dragendorff, for many years director of the Pharmaceutical Institute at Dorpat, in Russia, which, while he was there, had the highest reputation as a pharmaceutical training college and school of research. From the *Chemist and Druggist* we learn that Dr. Dragendorff was born in Rostock in 1836. After qualifying as an apotheker, he studied chemistry in the Heidelberg University, which he left in 1860 to become assistant to Prof. F. Schultze, in the chemical laboratories of the Rostock University. In the same year he graduated as Ph.D., his thesis being on the action of phosphorus upon some carbonates and borates. In 1862 he went to St. Petersburg to take charge of the *Pharmaceutischen Zeitschrift für Russland*, as editor, and of the laboratories of the Pharmaceutical Society there. While acting in that capacity his reputation grew, and his appointment as Professor of Pharmacy and Director of the Pharmaceutical Institute at Dorpat in 1864 was the beginning of thirty years' work which made the Dorpat Institute famous all over the world, for Dragendorff's skill as a teacher and discoverer of talent brought students to him from all quarters. He retired to his native town in 1894, and devoted his leisure to a monumental work on medicinal plants, of which at least one part has been published. He was best known to English pharmacists through his "Plant Analysis," a translation of which, by his former pupil, Henry G. Greenish, was published in 1883. His work on alkaloids was, however, that by which he is most entitled to fame. The mydriatic alkaloids were his special field, and his syntheses of conine and atropine are amongst the most brilliant achievements of modern chemistry. In 1885 the Pharmaceutical Society of Great Britain conferred the third Hanbury medal upon him.

THE Kew Observatory Committee have issued their Report for the year 1897. During that period the magnetic curves have been free from any very large fluctuations; the mean westerly Declination for the year was 17° 6′, and the mean Inclination, 67° 20′. The meteorological observations conducted for the Meteorological Council call for no special remarks; the electrograph has been in nearly constant operation since January 19. Several hours' record were lost owing to the trace being off the sheet; Dr. Chree states that it is difficult to see how such loss can be avoided without either duplicating part of the apparatus, or by risking possible loss of negative trace by shifting the position of the zero line on the sheet. Sketches of sun-spots were made on 165 days; it has been decided to discontinue the eye observations, owing to the elaborate photographic work now done elsewhere. Among the various experiments and researches in connection with the several departments we observe that attention has been given to the comparison of platinum and mercury thermometers at high temperatures, in view of repeated requests for direct high temperature verifications. Experiments are also being made as to the thermometric properties of different kinds of glass, the results of which will be eventually published. The usefulness of the institution is shown by the continual increase in the number of instruments submitted for verification; the increase during the year in question amounted to nearly three thousand. In addition a large number of watches and marine chronometers were received for trial.

A NUMBER of investigations have been made on the connection of various terrestrial phenomena with the period of rotation of the sun, but the results obtained have not been definite enough to establish the reality of a twenty-six-day period of meteorological phenomena. In connection with this question, Prof. Arthur Schuster subjects the methods of finding hidden periodicities—small periodic variations hidden behind irregular fluctuations—to vigorous analysis in *Terrestrial Magnetism* (March), with the object of introducing a little more scientific precision into the treatment of problems involving hidden periodicities, and of applying the theory of probability in such a way as to assign a definite number for the probability that the effects found by means of the usual methods are real, and not due to accidental circumstances. The methods described show the lines which investigations on the periodicity of phenomena should follow, and point to several interesting subjects to which they may profitably be applied. As to results already published, Prof. Schuster concludes:—"The general result of a critical examination of the published investigations on the twenty-six-day period leads me to think that, although the magnetic elements and the occurrence of thunderstorms seem to be affected by a period of twenty-six days and of its first multiple, the subject requires a good deal of further study before we can be sure as to the exact nature of the period. Even though it may be considered as proved, it must not be necessarily assumed that it is due to solar action. If it was a question merely of magnetic disturbances, there does not seem to be any great improbability, however, that some periodicity may be connected with the sun's rotation about its axis, especially at times of great sun-spot activity."

IN a short note in the *Comptes rendus* (No. 15, April 1898), M. Thiébaut gives us the result of his investigations on the frequency of the extra large tides which occur at the March equinox. He has used the number previously published in the *Connaissance de Temps* since the beginning of the century, and has shown that the relative magnitude of the coefficients of the tides at the syzygies vary notably from one year to another, but that the rule given below is subject to some exceptions. From the theoretical point of view this law of the variation of the coefficients assigns to the return of this great tide a period of about nine years if only one equinox is considered, or four and a half years if one indifferently takes account of the spring or autumn equinoxes. The principal cause of these variations he attributes to the movement of the moon's perigee, which completes one revolution in about 8 years and 310 days. Taking into account all the circumstances of the phenomenon he discovered a remarkable period of 412 days, at the completion of which the sun returns to the lunar perigee. This period he calls the "année périgéenne"; and it does not differ very much from two other interesting periods, one of 413·4 days, which corresponds to 14 lunar months (synodic), the other of 413·3 days, or 15 anomalistic months.

THE theory which attributes volcanic eruptions to disturbances produced beneath the earth's crust by luni-solar tide-generating forces would receive striking confirmation by the establishment of a connection between the periods of greatest volcanic activity and the phases of the moon which give rise to spring tides. Prof. Eugenio Semmola, writing in the *Atti del R. Istituto d'Incoraggiamento* (Naples), has compared the periods of maximum and minimum activity of Vesuvius with the phases of the moon during the two years from July 1895 to July 1897. The conclusions drawn from these observations are entirely of a negative character; the number of days of maximum and minimum activity being largely in excess of the number of lunations in the same period, and the fresh flows of lava being distributed fairly evenly between the moon's four quarters. A comparison of the more violent eruptions of Vesuvius from the year 1800 to the present time shows that in five of these the nearest phase of the moon was the new or full moon, and in the remaining five the nearest phase was the first or last quarter. It thus appears that no relation exists between the activity of Vesuvius and the phases of the moon.

THE *Journal de Physique* for April contains the continuation of an important paper, by M. A. Leduc, on the densities and molecular volumes of gases. M. Leduc has established, under the name of "law of molecular volumes," a limiting law, which he proposes as a substitute for the principle of Avogadro and Ampère. This law he applies to the calculation of the densities and coefficients of expansion of a number of gases, and every experimental determination appears to agree with the predicted results.

IN the same journal, M. J. Macé de Lépinay gives a proof that the fringes of caustics and the supernumerary arcs of rainbows can be regarded as true interference-fringes.—M. P. Morin considers the influence of the length of magnets on their mean intensity of magnetisation. In needles of the same material and cross-section magnetised to the point of saturation, the intensity of magnetisation and the magnetic density at the two ends are independent of the length of the needle, and the same is the case for all sections taken at equal distances from the extremities.

NEW magazines devoted to discussion of the Röntgen rays appear to be springing up in every direction. From St. Louis we have received the *American X-Ray Journal*, which is stated on the cover to be "a monthly devoted to the practical application of the new science and to the physical improvement of man." It is illustrated by very fair radiographs of fractures and dislocations, and a somewhat striking "skiagram" of a loaded Lebel rifle.

WE have received the second part of the *Annales d'Électrobiologie, d'Électrothérapie et d'Électrodiagnostic*. This new bimonthly journal deals with the applications of electricity to medical purposes, including the uses of Röntgen rays. In addition to original papers, a full bibliography of current literature is given. M. Félix Alcan, of Paris, is the publisher.

WRITING in the *Rendiconti del R. Istituto Lombardo*, xxxi., Signor Luigi de Marchi criticises the views advanced by Arrhenius on the causes of the variations of climate considered specially with reference to the influence of carbonic acid on the temperature of the ground (see *Philosophical Magazine*, 1896, p. 237). He considers that Arrhenius is in error (1) in treating as negligible the variations in the solar radiation produced by even considerable increases in the carbonic acid and watery vapour of the atmosphere; (2) in attributing a definite physical meaning to the coefficient which represents the coefficient of emission of a fictitious stratum whose radiation is equivalent to that of the atmosphere; and (3) in assuming that the same coefficient also represents the coefficient of absorption of the stratum in question for terrestrial radiations.

THE Astronomical and Physical Society of Toronto seems to be in an ever flourishing condition, judging from the *Transactions* which appear from time to time. The latest volume, for the year 1897, which includes the eighth annual report, displays the Society's activity by the numerous and varied papers which were communicated during the past twelve months. Among these papers may be mentioned an historical sketch of the Greenwich *Nautical Almanac*, periodicity of magnetic elements, the November meteors of 1832 and 1833, the variable star Algol, &c. Mr. G. E. Lumsden made a short communication on the best method of making the work of the Society valuable, and his suggestions are such that any other society might learn a good lesson by following them. We hope to see this scheme carried out successfully, as its lines, corresponding to those of the subdivision of labour of the British Astronomical Association on this side of the Atlantic, are undoubtedly sound.

SEVERAL interesting reminiscences of the Edinburgh Medical School in the 'fifties and 'sixties are given in an article in *Chambers's Journal* for April. The teachers in the University at that time—Syme, Simpson, Goodsir, Christison, Hughes-Bennett, Playfair, Douglas Maclagan, Laycock, Turner, Allmann, Balfour, Henderson and the rest—all take prominent places in the history of the science and practice of medicine. Referring to Sir James Simpson and the use of chloroform, the writer remarks that deaths under this anæsthetic were almost unknown in his days. He says: "We hardly ever used a stethoscope to examine the heart, or felt the pulse, and the patients did not die. . . . Both Simpson and Syme taught that chloroform should be inhaled from being sprinkled on a towel, the two golden rules being to see that the vapour was properly diluted by the surrounding air, and to watch the breathing, holding the towel some inches from the face. It may be a coincidence merely; but if so it is remarkably strange that, while the chloroform has not changed, while the constitutions of the patients have not changed, where the use of an inhaler is the rule, there are frequent deaths from chloroform; whilst in Scotland and Ireland, where the use of an inhaler is the exception, deaths are proportionately rare."

SOME interesting investigations on the behaviour of micro-organisms in the presence of compressed gases have been published by G. Malfitano in the *Bollettino della Società medico-chirurgica di Pavia*. The more importance attaches to these researches, inasmuch as compressed carbonic acid gas has been lately regarded by some authorities as endowed with trustworthy antiseptic or sterilising properties. Malfitano's investigations do not, however, support this view. A large number of experiments were made with pure cultures of various bacteria in a dry condition, exposed for periods of time varying from 20 to 64 hours to a maximum pressure of 55 atmospheres. Whilst some bacteria were destroyed, amongst which we note *B. coli communis*, *B. anthracis*, *saccharomyces cerevisiæ*, the hyphomycetes, and *B. subtilis*, invariably withstood this influence. In other experiments we find again a large number of bacterial varieties exposed to pressures varying from 60–25 atmospheres, with the result that whilst typhoid and cholera bacilli, the *B. prodigiosus*, staphylococcus pyogenes aureus, and citreus and other well-known varieties succumbed more or less rapidly, *B. subtilis*, *B. mesentericus*, Tyrothrix, and *B. œdematis* invariably survived. It should be mentioned that no permanent biological modification in the bacteria employed was observed to result from exposure to compressed carbonic acid gas. Judging by experiments carried out to ascertain the relative effect of length of exposure to, and degree of pressure of this gas upon bacteria, it would appear that the latter factor was of more importance than the former. Endeavours were made to, if possible, increase the bactericidal potency of the gas, by submitting bacteria to the *interrupted* action of the gas. For this purpose subtilis bacilli, containing their well-known hardy spore forms, were employed. These bacilli were exposed for 20 hours to the gas at intervals of 24 hours, this being repeated four times, but no different result followed. It will be remembered that alternately freezing and thawing bacteria tends to increase the sensitiveness of, at any rate, some bacteria to extreme cold. The author tried, finally, the effect of liquefied carbonic acid gas upon the vitality of the spores of *B. subtilis*; but from this test, also, they emerged triumphant, suffering no damage at all.

THE current number of the *Journal of the Sanitary Institute* contains papers on a variety of subjects; amongst them we notice one on poisoning by canned foods, by Dr. F. Brown. The writer has collected all the reports which have appeared in medical journals since the year 1879 of cases of poisoning from tinned foods. As regards fish and meat thus preserved, the poisonous effect is probably due to the presence of ptomaïnes, and the only way of preventing this dangerous deterioration is to take all possible precautions that the materials used are of the very best quality, and that the canning process is carried on under the strictest hygienic conditions. Canned fruits do not appear to have been responsible for any fatal cases of poisoning, but salts of tin and zinc are frequently present in such materials. In some instances, especially in cans containing pears and apricots, lead in quantities sufficient to give rise to lead-poisoning was found, whilst in other canned fruits the apricots had acquired a metallic taste from the amount of metal present. As all canned foods are better for being used soon after canning, a good plan would be to state on each tin the date of its canning, so that the public may have some guide as to the quality of the article they are purchasing.—A paper on the contamination of water supplies by encampments of hop-pickers, gipsies, &c., is contributed by Miss Chreiman. Although some allowance must be made for the unfortunately exaggerated style of the writer, there can be no doubt that she has done good service in once more bringing before the general public the highly unsatisfactory conditions under which hop-picking is now carried on. Possibly the Maidstone typhoid epidemic of last autumn may succeed in rousing local authorities to take effective measures to provide for, and officially organise, this periodic invasion of country districts. Surely, for example, the sleeping on "beds of short straw, beneath which was a mattress of cattle manure two spades deep," ought to be an impossibility at the close of the nineteenth century.

A PRELIMINARY report, by Mr. Milton Whitney, upon the soils of the principal tobacco districts in the United States has just been published by the United States Department of Agriculture. The tobacco-plant readily adapts itself to a great range of climatic conditions, and will grow on nearly all kinds of soil, but the flavour and quality of the leaf are greatly influenced by the conditions of the climate and soil. So far as climate is concerned, Mr. Whitney remarks that experience is the only safe test as to the class of tobacco which can be produced under given climatic conditions. Ordinary meteorological records appear to be of little value in determining this point; for the tobacco-plant is more sensitive to meteorological influences than the instruments. Even in such a famous tobacco region as Cuba, tobacco of good quality cannot be grown in the immediate vicinity of the ocean, or in certain parts of the island, even on what would otherwise be considered good tobacco lands. This has been the experience also in Sumatra and in the United States, but the influences are too subtle to be detected by ordinary meteorological instruments. Little, therefore, can be said at the present time in regard to the suitable climatic condition for tobacco of any particular type or quality. Under given climatic conditions, the class and type of tobacco depend upon the character of the soil, especially on the physical character of the soil, upon which it is grown. The texture or coarseness of the soil grains, and the water content, which is largely dependent upon it, appears to determine and control the distribution of the different widely distinct types of tobacco. This conclusion is borne out by Mr. Whitney's mechanical analyses of tobacco soils, consisting of separating the particles of soils into grades of different sizes. The results show a very marked difference in the texture and physical properties of the soils adapted to the different classes, types, and grades of tobacco, and give a basis for the classification of tobacco soils.

DR. SUPAN has a short article on antarctic exploration in *Petermann's Mittheilungen*. The German and English proposals are described, and Brückner's calculations of climatic periods quoted to show that the present is an exceptionally favourable time for penetrating southward. The period of Ross's voyages was probably much colder than the average.

DR. ERICH VON DRYGALSKI publishes in *Petermann's Mittheilungen* a paper on ice movements, their physical causes, and their geographical effects. The paper is in effect an abstract of results of the work of the Greenland expedition of the Berlin *Gesellschaft für Erdkünde*, published in full as a separate volume in the course of last year.

THE April issue of the *National Geographical Magazine* is a Klondike number, and contains several trustworthy articles on the conditions, resources and future of Alaska and the Yukon gold-fields. A map of the gold- and coal-fields of Alaska, and showing also the principal steamer routes and trails, on a scale of about fifty-seven miles to one inch, accompanies the papers in the magazine.

NOS. 5 and 6 of vol. xxxii. of the *Zeitschrift der Gesellschaft für Erdkünde zu Berlin* contain papers by Herr E. de Martonne on the hydrography of the basin of the Upper Nile, by Dr. A. Galle on Dr. Philippson's measurements of heights on the Greek islands of the Ægean, on a new map of the eastern part of New Britain by Freiherr von Schleinitz, and on journeys in the Upper Amazon region by Dr. A. Rimbach. Herr E. de Martonne's paper is a review of the present state of knowledge regarding the Upper Nile, with a new orographical map and a sketch of seasonal distribution of rainfall.

AMONG the papers in the current number (April) of the *Journal* of the Royal Horticultural Society are several of scientific interest, in addition to papers on progress in the methods and results of cultivation. Mr. C. C. Hurst describes some curiosities of orchid breeding, and his experiments and observations on hybrids are of distinct value. Prof. F. W. Oliver has a paper on the depth in the soil at which plants occur, and Prof. Geo. Henslow one on chrysanthemum sports.

AMONG reprints of important papers from the *Botanical Gazette* we have received:—Winter characters of certain sporangia, by Charles J. Chamberlain; contributions to the life-history of *Ranunculus*, by Prof. Coulter; and a general review of the principal results of Swedish research into grain-rust, by Prof. J. Eriksson. The Swedish professor distinguishes eight distinct forms of *Puccinia* which produce rust; these being again arranged under a number of secondary forms, dependent on the host-plant, most of the primary forms being parasitic on several different species.

THE views with regard to the origin of vertebrates, put forward by Dr. W. H. Gaskell, F.R.S., in his presidential address to the physiological section of the British Association, at the Liverpool meeting in 1896, are to be stated more fully in the *Journal of Anatomy and Physiology*. The April number of the *Journal* contains the first of a series of papers in which Dr. Gaskell will fill in the details of evidence which were necessarily omitted from his address.

A COPY of Mr. Joseph Baxendell's report on the results of observations made at the Southport Corporation Meteorological Observatory during 1897 has been received. A noteworthy feature of the report is a comparative table showing the mean annual meteorological statistics for every health resort in the United Kingdom known to possess a meteorological station. The systematic work done in the meteorological department of the borough of Southport should encourage accurate health resort climatology in general, and municipal meteorology in particular.

INCLUDED in the "Bergens Museums Aarbog" for 1897 is Prof. R. Collett's interesting paper on Beavers in Norway, with twelve plates reproduced from photographs of beaver lodges and dams. The subjects of other papers are:—Generalisation of some algebraic equations which present themselves in the theory of elliptic functions; a Sowerby Whale (*Mesoplodon bidens*, Sow.), stranded on the west side of Karmö Island; histological studies of the structure of the eyes of certain marine annelids; a generalisation of the Lamé equation; the Lepidoptera of North Bergen county; physical conditions and plankton of Puddle fiord.

IN a memoir which appears in the *Proceedings* of the U.S. National Museum (vol. xx. pp. 1-421, 1897), Mr. S. H. Scudder describes in detail and discusses the classification of a group of grasshoppers which forms the prevailing type of orthopteran life throughout North America—the short-horned grasshopper commonly seen in the United States, its best-known representative to the world at large being the destructive migratory Rocky Mountain Locust. The title of Mr. Scudder's paper is "Revision of the Orthopteran Group Melanopli (Acridiidæ), with special reference to North American forms."

THE natural history societies of our public schools deserve encouragement, for they create interest in natural things and phenomena, and lead inquiring minds to make observations for themselves. The reports of three such societies, namely those of Rugby, Wellington, and Cheltenham, showing the results of observations, and containing abstracts of lectures, have been received, and each of them is a creditable production. Among the papers which call for special attention is an essay upon the birds of the Oxford district, by Mr. F. Sidgwick, in the Rugby Society's report; and one on birds and birds-nesting, by Mr. C. Montford, in the Cheltenham Society's report.

ARCHÆOLOGISTS will be interested in a paper on "Dwellings of the Saga-time in Iceland, Greenland, and Vineland," by Cornelia Horsford, which appears in the *National Geographic Magazine* (March). The Saga-time began with the colonisation of Iceland in 875, and lasted for about 150 years, but little definite knowledge exists as to the forms of the dwellings in those days. The paper is illustrated by plans of Norse ruins (so far as they are known) in Iceland and Greenland, and of a supposed Norse ruin in Massachusetts. It will enable a comparison to be made between the different dwellings of the Northmen and those of the native tribes of North America, from the magnificent ruins of Copan to the long, narrow houses of the Iroquois.

PROF. WILLIAM SOMERVILLE'S sixth annual report on experiments with crop and stock in the counties of Cumberland, Durham and Northumberland, provides an excellent example of useful technical education assisted by County Councils. In the work of agricultural demonstration described in the pages of the report, the Durham College of Science was associated with the Councils of the counties above referred to, and the information given will be distinctly valuable to the agriculturists of these counties. Of especial importance are the results of rotation experiments which have been carried on for four years on three Northumberland farms. The results obtained at these stations are tabulated, but the detailed discussion of the rotation experiments has not yet been completed.

THE fourth number of "The Psychological Index"—a bibliography of the literature of psychology and cognate subjects for 1897, compiled by L. Farrand and Howard C. Warren—is a most useful publication for psychologists. The papers are well classified, and there is an index of authors; so it is easy to find what contributions have been made to the various branches of the science, and what the various investigators have done. There are 2465 titles in the Index, thus indicating considerable activity in psychological science. The Index is issued in connection with the *Psychological Review,* which is published bi-monthly by the Macmillan Company.

A *Bulletin* (No. 13, new series), containing a compilation, by Dr. L. O. Howard, of recent laws and regulations against injurious insects, and especially the San José scale, has been issued by the U.S. Department of Agriculture. The information given will be of interest to persons engaged in trade with living plants, and to horticultural and agricultural societies and others wishing to propose legislation of the kind described. Another *Bulletin* (No. 12), just issued by the U.S. Department of Agriculture, gives an account of the spread of the San José scale in the United States during the last two years, and of the work which has been done by economic entomologists in the effort to subdue it.

THE latest phases of the controversy concerning the place where John Cabot first landed in North America four hundred years ago, are presented in a paper by Dr. S. E. Dawson, on "The Voyages of the Cabots," published in the *Transactions* of the Royal Society of Canada for 1897. Dr. Dawson concludes "that there is no physical or geographical reason *à priori* why Cape Breton may not have been Cabot's landfall, and that the voyage was intended to be upon a westerly course. It will also appear that all the conditions existing upon the North Atlantic tend to make a westerly course swerve to the south, and that there is, therefore, a strong preponderance of probability in favour of a landfall at Cape Breton." Positive evidence of contemporary documents is shown to point to the same conclusion.

MESSRS. MASSON AND CO., Paris, will shortly publish the following works of science:—"L'Anatomie comparée des animaux basée sur l'embryologie," by Prof. Louis Roule; "Précis de Botanique médicale," by Prof. L. Trabut; "Eléments de Botanique," by Prof. Ph. van Tieghem.

MR. T. R. DALLMEYER has just published a useful little book entitled "A Simple Guide to the Choice of a Photographic Lens." This book seems to be exactly suited to the requirements of a whole host of photographers, especially amateurs who prefer to have their information retailed concisely and simply by one who knows. A great feature of these thirty pages is the appeal to diagrams which illustrate more clearly than words many fundamental facts regarding lenses and their behaviour. Four excellent platino-bromide reproductions are inserted, to illustrate the capabilities of the author's new universal stigmatic lens, Series ii. F/6, which does the work of practically four ordinary lenses.

THE firm of Gustav Fischer, Jena, announces for early publication the following new works and new editions:—"Ueber Herzbewegung und Herzstoss," by Dr. Ludwig Braun. This volume will contain the results of an experimental study of movements of the heart, analysed by means of a kinematograph.—"Die Bakteriologie in der Milchwirtschaft," by Dr. E. von Freudenreich.—The second part of Dr. Oscar Hertwig's work on "Die Zelle und die Gewebe," dealing with the general anatomy and physiological properties of the tissues.—"Beiträge zur Klinik der Rückenmarks-und Wirbeltumoren," by Dr. H. Schlesinger.—The first section of "Mitteilungen aus der Augenklinik," by Dr. J. Widmark.—The fourth enlarged edition of Dr. Robert Wiedersheim's "Grundriss der vergleichenden Anatomie der Wirbeltiere."

THE Chemical Publishing Company, Easton, Pennsylvania, has published a second, thoroughly revised edition of "Laboratory Experiments on the Class Reactions and Identification of Organic Substances," by Dr. A. A. Noyes and S. P. Mulliken. A sixth edition of Mr. P. McConnell's serviceable "Notebook of Agricultural Facts and Figures for Farmers and Farm Students" has been published by Messrs. Crosby Lockwood and Co.—The present state of knowledge of Röntgen radiation and its practical applications is well stated in the second edition of "Practical Radiography" by A. W. Isenthal and H. Snowden Ward, published by Messrs. Dawbarn and Ward. Many of the illustrations in the book are very fine.—A revised and enlarged edition (the sixth) of Messrs. Marion and Co.'s well-known "Practical Guide to Photography" has just been issued.

THE additions to the Zoological Society's Gardens during the past week include four Silver Pheasants (*Euplocamus nycthemerus*) from China, presented by Mr. H. J. Veitch; a Common Barn Owl (*Strix flammea*), captured at sea, presented by Captain George Innes; a Black-winged Peafowl (*Pavo nigripennis*, ♂) from Cochin China, presented by Mr. Richard H. J. Gurney; four Undulated Grass Parrakeets (*Melopsittacus undulatus*) from Australia, presented by Mr. Aitchinson; a Black-bellied Sand Grouse (*Pterocles arenarius*) from Asia, a Pin-tailed Sand Grouse (*Pterocles alchata*), South European, a Rosy Bullfinch (*Erythrospiza githaginea*) from Algeria, presented by Mr. E. G. B. Meade-Waldo; two Common Bluebirds (*Sialia wilsoni*) from North America, two Yellow-bellied Liothrix (*Liothrix luteus*) from China, an Amaduvade Finch (*Estrelda amandava*) from India, a Red-bellied Waxbill (*Estrelda rubriventris*), a Crimson-eared Waxbill (*Estrelda phænicotis*) from West Africa, presented by Miss Edith M. Kemp Welch; four

Amaduvade Finches (*Estrelda amandava*), a Green Waxbill (*Estrelda formosa*), two Black-headed Finches (*Munia malacca*), two Chestnut-bellied Finches (*Munia rubro-nigra*), three Indian Silver-bills (*Munia malabarica*) from India, a Common Waxbill (*Estrelda cinerea*), three Orange-cheeked Waxbills (*Estrelda melpoda*), two Red-bellied Waxbills (*Estrelda rubriventris*), a Paradise Whydah Bird (*Vidua paradisea*), a Grenadier Weaver Bird (*Euplectes oryx*) from West Africa, three Banded Grass Finches (*Poëphila cincta*) from Queensland, a Bar-breasted Finch (*Munia nisoria*) from Java, a Maja Finch (*Munia maja*) from Malacca, a Chestnut-eared Finch (*Amadina castanotis*) from Australia, presented by Miss Petrocochino; two Black Rats (*Mus rattus*) from the Channel Islands, presented by Mr. J. Ernest Ardron; a Common Otter (*Lutra vulgaris*), British, presented by Mr. A. P. Ashburnham; three Hairy-footed Jerboas (*Dipus hirtipes*) from North-east Africa, presented by Miss Baird; a Green-cheeked Amazon (*Chrysotis viridigena*) from Colombia, deposited; a Collared Fruit Bat (*Cynonycteris collaris*), a Yellow-cheeked Lemur (*Lemur xanthomystax*), a Crested Porcupine (*Hystrix cristata*), two Squirrel-like Phalangers (*Petaurus sciureus*), a Red Kangaroo (*Macropus rufus*), born in the Gardens.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN MAY :—

May 2. 11h. 24m. to 12h. 11m. B.A.C. 4006 (mag. 5·7) occulted by the moon.
2. 21h. Jupiter in conjunction with moon. Jupiter 6° 58′ N.
6. Vesta (mag. 6·5) in opposition to the sun. In Libra.
7. 6h. 36m. α Scorpii (Antares) in conjunction with moon. α Scorpii, 1¼° S.
7. 12h. Saturn in conjunction with moon. Saturn 5° 7′ N.
11. 13h. 16m. to 13h. 51m. B.A.C. 7263 (mag. 6) occulted by moon.
13. Uranus 52′ S. of β Scorpii (mag. 3).
15. Venus. Illuminated portion of disc 0·923.
15. Mars. " " " 0·936.
18. 18h. Venus in conjunction with Neptune. Venus 2° 19′ N.
20. Saturn. Outer minor axis of outer ring, 18″·69.
20. Ceres 16′ N. of β Geminorum (Pollux).
22. 4h. Uranus in opposition to the sun. In Scorpio.
22. 6h. 54m. to 7h. 32m. Venus occulted by moon.
24. Encke's Comet arrives at perihelion.
29. 22h. Saturn in opposition to the sun. In Scorpio.
30. 5h. Jupiter in conjunction with moon. Jupiter 7° 1′ N.

DOUBLE AND MULTIPLE SOUTHERN STARS.—The observation of double and multiple stars in the southern heavens has never been attempted on a large scale, although several observers have turned their attention to these bodies with not very large apertures. Sir John Herschel, in his southern sweep for nebulæ and clusters, was enabled to detect over 2000 new double stars; but his chief interest was more for the close examination of the former celestial objects than for the search for double stars. Since that time the Sydney Observatory, the Cape Observatory, and the Harvard observers at Arequipa have done much to promote our knowledge of this class of southern stars. A search on a large scale has recently been undertaken by Dr. T. J. J. See, who was invited by Mr. Lowell to undertake a survey of the southern heavens for the discovery and measurement of new double stars and nebulæ with the 24-inch refractor, which had just been completed by the Clarks. In the *Astronomical Journal* (Nos. 431-432) Dr. See gives us some details of his plan of work, together with the first part of the catalogue of new double stars. In this survey Dr. See was aided by Mr. Cogshall. The observing station was first at Mars' Hill, Flagstaff; next in Mexico, in the western part of Tacubaya; and then again at Flagstaff, the telescope in each case being dismounted and re-erected.

The region of the sky embodied in this work includes the entire zone between −20° and −45°, and the more southern region swept over in Mexico lies between −45° and −65° between 4h. and 16h. Right Ascension. Dr. See states: "In the course of this work it is certain that we have examined carefully not less than one hundred thousand stars, and many of them doubtless on several occasions." All the star places have been referred to the equator and mean equinox of 1900·0, and in each case the colours are given after a terminology which was found best to describe the tints of the spectrum. To give an idea of the quality of the object-glass used, and the excellent atmospheric conditions at Flagstaff, we may mention that an object was not considered difficult unless it was below 0″·3, or fainter than the 14th magnitude for fairly wide objects. Dr. See proposes to arrange the final catalogue in two parts: the first giving the new doubles, and the second doubles recognised by previous observers. He further uses the symbol λ to denote "stars discovered at the Lowell Observatory," and an index 1 being affixed to this letter in the first catalogue, and other numbers in subsequent catalogues. When completed, this great work will prove a most valuable contribution to our knowledge of many interesting systems in the southern hemisphere.

COMET PERRINE.—The following is a continuation of the ephemeris given previously in this column :—

12h. Berlin Mean Time.

THE MANORA OBSERVATORY.—In a recent number of the *Naturwissenschaftliche Wochenschrift* (Band xiii. No. 14), Herr Leo Brenner gives a condensed account of the observations made at the Manora Observatory during the past year. As usual, the observations are chiefly restricted to minute examinations of the surface markings of planets. The article is illustrated by reproductions of the observatory and instruments and drawings of the surface markings of some of the planets. Herr Brenner refers to the question that has been raised regarding the financial condition of the observatory. In his concluding remarks he adds: "For the main part my work this year will depend on whether a change occurs in the financial condition of the observatory, or whether I shall be obliged, as formerly, to waste my time in writing worthless scientific articles."

THE HARVARD COLLEGE OBSERVATORY.—The fifty-second annual report of the director of the Astronomical Observatory of Harvard College gives us an idea of the immense amount of work which is being carried on so successfully under his supervision. Not only are extensive investigations undertaken, but they are brought to completion by the liberal staff with which he is provided. After referring to the large endowment for current expenses which renders such assistance possible, Prof. Pickering adds that as regards permanent plant they are far behind other observatories even of the second class. That this will be soon remedied there is no doubt; and Prof. Pickering has the happy faculty of knowing from which direction such donations will come, for he says, "the need of modern buildings is most likely to be supplied by gifts or bequests from persons whose names should be attached to them. For instance, a library building in which the clerical work of the institution could be performed is greatly needed. A modern machine-shop to replace our present workshop would form an excellent memorial of one who had been interested in the application of the mechanic arts to scientific uses." As usual, each of the instruments has been used for extensive investigations. The east equatorial has been employed for photometric light comparisons of variables mostly with the new polarising photometer, while the west instrument has been used for similar observations of variables and comparison stars. The meridian circle and meridian photometer have also been continuously employed, Prof. Pickering having worked with the latter on 152 nights, and made 100,052 photometric settings. The researches planned for this latter instrument are, we are told, approaching completion, 860,000 measures of about 40,000 stars having been made during the last twenty years. Both the 8-inch telescopes have been used for photographing stellar spectra, the number of photographs obtained being 6054. The 11-inch Draper telescope has been employed for photographically recording the satellites of Jupiter undergoing eclipse, and variables of the Algol type. Mr. King, who has been investigating the effects of differential refraction and flexure on the form of the photographic images, has found that an equatorial should never be driven on sidereal time, but that satisfactory images have been obtained by photographing at suitable hour angles with a mean time driving clock, the rate being wholly corrected by the refraction in right ascension. Experiments are now being made to introduce a flexure correction automatically. In this connection it is interesting to refer to the work done by Dr. Rambeau. With regard to the other departments under the direction of Prof. Pickering, we must limit ourselves here to mentioning them: namely, the Boyden department at Arequipa, where the new Bruce photographic telescope has been erected, and the Blue Hill Observatory, although they have both been contributing valuable observations during the last twelve months.

THE NATURE AND HABITS OF PLINY'S SOLPUGA.

ALTHOUGH next to nothing is known of the past history of the spider-like creatures discussed in the following pages, it is tolerably certain that since glacial times they have been confined in their distribution, so far as Europe is concerned, to Spain, Greece and South Russia. Since, therefore, they were certainly unknown to our British and Anglo-Saxon ancestors, and probably also to the early Romans, it is not surprising that the English language has no name for the group of which they are members. To the ordinary Englishman they are spiders, and as spiders or tarantulas they are usually described by travellers who have come across them in India, Egypt and elsewhere. The Greeks, on the contrary, who were doubtless acquainted with the species inhabiting their own country and Asia Minor, seem to have recognised them from the ordinary spider, since they had a distinctive name for each of the two groups. The spiders were called Arachne (ἀράχνη); the others Phalangium (φαλάγγιον), in allusion to their five pairs of long-jointed limbs. Ælian, for example, tells how a country in Æthiopia was deserted on account of the appearance of incredible numbers of Scorpions and Phalangiums. But Pliny, when quoting the same story, introduces Solpuga[1] in place of Phalangium. And since the latter is now used in systematic zoology for a totally different group, namely for the so-called Harvest or Long-legged Spiders, so abundant throughout Europe, no further reason need be given for adopting Pliny's name for the species now under discussion.

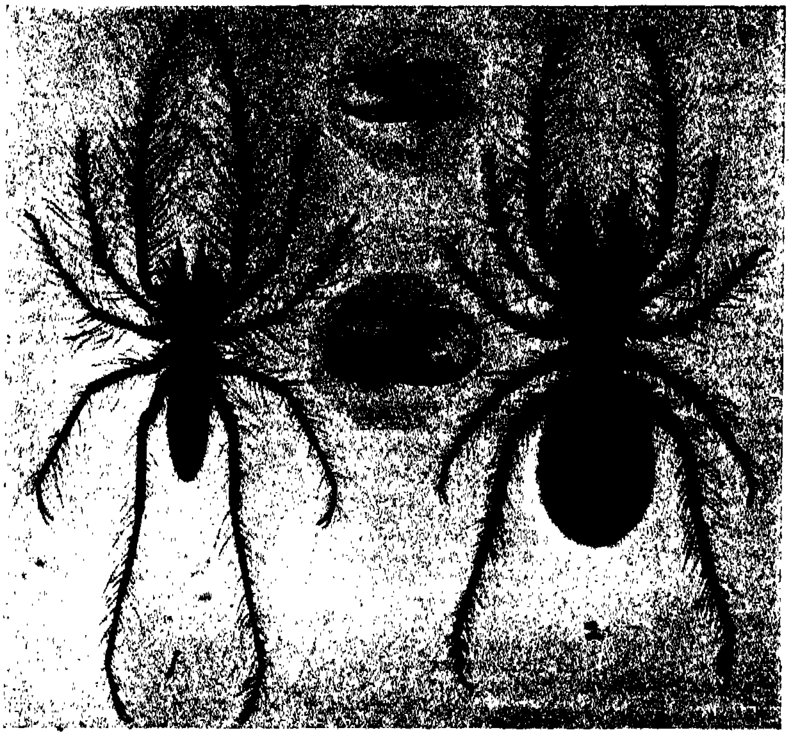

FIG. 1.—Indian Solpuga (*Galeodes fatalis*).—1, male; 1*a*, jaw of male seen from the side; 2, female; 2*a*, jaw of female seen from the side. (Figs. 1 and 2 reduced to three-fourths the natural size.)

So much by way of preface. But before leaving the ancient history of the Solpuga, it may be interesting to mention a suggestion that has been made to the effect that the Hebrew word translated Mouse in the Old Testament referred to some sort of Solpuga; and that the sores, the emerods (hæmorrhoids), from which the Philistines suffered, resulted from the bites of these creatures. In support of this supposition may be urged the unmistakable resemblance to mice presented by some of the smaller, dark-coloured, short-legged species, with their hairy bodies and rapid movements, which occur both in Egypt and Syria; and the statements of travellers to the effect that at the present time they inflict painful bites upon people when asleep in the desert at night.

It is beyond the scope of the present article to deal with the many points of interest connected with the anatomy of these animals. Nor is it necessary to point out all the distinctive features which serve to separate them from the true spiders, the only members of the class Arachnida with which they are likely to be confounded. Suffice it to say that the term spider, doubtless a corruption of spinner (spinster), is technically applied exclusively to the familiar web-spinners, and that no silk glands exist in any members of the order Solifugæ.

The general form is well shown in the annexed illustration depicting the male (Fig. 1) and the female (Fig. 2) of a North Indian species called *Galeodes fatalis*. As will be seen, the sexual differences are very striking, the male being both smaller and lighter in build, with the head narrower and the jaws less bulky; the legs, on the contrary, are unmistakably longer. This correlation between lightness of body and length of limb points to much greater activity on the part of the male, a superiority which no doubt stands him in good stead at the pairing time, when the female has a habit, it is alleged, of killing and devouring her less powerful mate. Again, in addition to being smaller, the jaws of the male (Fig. 1*a*) are always less strongly toothed than those of the female (Fig. 2*a*), and are furnished on the upper side with a peculiar organ of unknown function called the *flagellum*.

In both sexes, but especially in the female, the jaws attain a development unequalled elsewhere in the class Arachnida (Spiders, Scorpions, Solpugas, &c.). They are, in fact, admirably adapted for the purpose of crushing hard-shelled beetles and other insects. But they also have another duty to perform, namely, that of digging; for the females, at least at the breeding season, excavate subterranean burrows for the protection of themselves and their young. The process has been observed in the case of the species here figured. Choosing a suitable spot, the female proceeded to cut away the earth in a circle with her jaws, then kicked away the loosened fragments with her legs, or scraping them together into a heap with the palpi [the long front pair of legs], pushed the pile by main force from the entrance of the burrow. At its opposite end the eggs, about fifty in number and resembling a mustard-seed in size and shape, were laid, and hatched about a fortnight afterwards. For three weeks the young showed no sign of movement. They then moulted for the first time and started to crawl about on their own account, little copies in miniature of their mother, who mounted guard at the entrance and resolutely repelled all intruders, snapping without hesitation at every object thrust into the burrow.

---

[1] This word is, perhaps, a corruption of *Solifuga* or *Solipugna*, which seem also to have been in use. The former means a creature which flees from the sun; the latter one that battles against it, and so hates or is intolerant of it.

Some species of Solpuga are known to be diurnal, and have been met with roaming abroad in the full glare of the tropical sunshine. From this habit they are known to the Spaniards of Santiago as "Arañhas del Sol" (sun-spiders). For the most part, however, they are nocturnal, and in certain localities favourable to their development prove a great nuisance to travellers camping out. Olivier, for example, describes how they would come into his tent in Mesopotamia at night, attracted by the light; and Mr. Guy Marshall informs me that an acquaintance of his, when encamped on the Hartley Hills, Mashonaland, was forced to shift his quarters on account of the invasion of his tent by a number of enormous spiders, evidently, from his description, a large Solpuga, which entered at night when the lamp was burning and rushed about at lightning speed. In such occurrences as these is doubtless to be found the substratum of truth upon which Ælian based his story of the desertion of the tract in Æthiopia on account of the Scorpions and Phalangiums.

Nothing in the way of animal life, provided it be of suitable size, comes amiss as food to the Solpuga, which is strictly carnivorous in diet. It is true that stories are told of the killing and eating of small vertebrates, like lizards, mice, birds, and bats. Nevertheless the staple article of their diet no doubt consists of insects of various kinds, ranging in size from ants to moths, beetles, or grasshoppers. A species which frequents the houses in Denver, Colorado, is said to be of service to mankind on account of its partiality for bed-bugs, a fact of some interest as showing that the strong stench of cyanide of potassium emitted by these parasites is no protection against the attacks of the Solpuga. Another kind living in Mashonaland, and known as *Solpuga sericea*—an elegant little species striped black and yellow, with long silky white hairs upon the hind legs, which, when running, resembles a tuft of thistle-down blown before the wind—feeds largely upon white ants; though Mr. Guy Marshall, my informant concerning its habits, has noticed that they eat jumping spiders of the family Attidæ, as well as small moths and beetles. When searching for food they may be seen running about at a great pace in the hot sunshine, and every now and again stopping to rest for a few seconds beneath the shade of a stone or leaf, only to rush off again without the least warning. Often when going at full speed they will stop abruptly and begin hunting and feeling around a small spot, irresistibly calling to mind the behaviour of a dog checked in mid-course by the scent of game. The white-ants they feed upon belong to a species which, instead of making a mound, builds mud tunnels along the surface of the ground amongst dead-leaves and sticks. Upon discovering such tunnelling the Solpuga follows it up, carefully examining it all the way, then suddenly breaks through the mud-wall and extracts a white ant. But whether the proximity of the insect is discovered by hearing or scent is at present unknown. This species is an expert climber, and has been seen to ascend trees to some height above the ground in search of prey. Similar stories are told of the climbing powers of other species from different parts of the world; and Mr. A. Carter informs me that in Egypt it is no uncommon thing to see a Solpuga (*Galeodes arabs*) climbing on to a table to get at the flies. To capture such quick and wary insects the Solpuga adopts the tactics of the hunting-spider; instead of making a furious dart, as it would if the prey in sight were a beetle, it proceeds to stalk the flies in the most wary fashion, creeping towards them with such slowness and stealth that the movements of the legs are almost imperceptible, yet all the while drawing gradually nearer and nearer; then like a flash of light the intervening space is traversed, and the insect struck down and captured.

Even in the case of so redoubtable an adversary as a scorpion, there is no hesitation on the part of the Solpuga in advancing to the attack. J. G. Wood tells us how at the outset of one such encounter the Solpuga by good fortune severed at one snap the scorpion's sting, and made short work of him afterwards. Nevertheless such an end to the contest is the exception rather than the rule; for in addition to some evidence on this head supplied by Mr. Trimen, Mr. Carter informs me that he has repeatedly witnessed encounters in Egypt between the common Solpuga (*G. arabs*) and the sand-scorpion of that country (*Buthus quinque-striatus*); but though the two are well matched for size, the scorpions never came off second best, in spite of the incomparable advantage in point of activity enjoyed by their adversaries.

Striking is the difference in appearance between a Solpuga fasting and a Solpuga full fed. In the former the abdomen shrivels up, the segments shrinking one within another like the several pieces of a half-closed telescope; in the latter the expansion is carried to such an extent that the distended abdomen much resembles a short thick sausage, far surpassing in size and weight the rest of the body and limbs. This is brought about by the imbibition of water and of the fluid and semi-fluid tissues of their prey. In support of their water-drinking propensities, the following passage, written by the Soudan war correspondent to the *Standard* (October 19, 1897), may be cited: "One day in my tent [at Kerma] I heard a rustle like that of a silk dress. A big, ugly, yellow hairy beast, with nippers like a crab, was moving fast as a mouse over the moist ground near the zeer [porous water jar] in the corner of my tent. At last he settled down to suck the water from the sides of the jar." The writer of the passage just quoted had previously spoken of this animal as the "famous abu-shabat, the terror of the Soudan in the way of spiders, as large as your hand and ten times more venomous than a scorpion."

This question of the poisonous nature of the Solpuga's bite is one that has attracted much attention. There is no doubt, however, that in the strict sense of the word they are not venomous at all. Nevertheless the jaws of the larger species are capable of giving a nasty and painful bite, and it is intelligible that a severe sore of long duration might result from such a wound if the Solpuga had been previously feeding upon septic matter, or if the sufferer were at the time addicted to scurvy or were in a weak state of health from any other cause. This, quite apart from other reasons, is sufficient explanation of the fact that the native inhabitants of almost all the countries where these animals are found look upon them with horror and fear on account of their alleged ferocity and venom. The natives of Somaliland, however, seem to be an exception to the general rule, for although the Solpugas are remarkable for size and abundance in that country, the Somalis, writes Mr. Parkinson, do not regard them as noxious, and have no names for things so unimportant. The dwellers in Baku on the Caspian, on the contrary, declare the Falangé [*Galeodes araneoides*] to be especially poisonous after emerging from its winter sleep, and, according to Mr. Rowland, believe that to counteract the effects of the poison it is necessary to rub the wound with the carcase of the Solpuga after first steeping it in boiling oil. Perhaps it is needless to explain to those who know the Asiatic that our subjects in Hindostan are firmly convinced of the deadly nature of the Jerrymanglum.[1] The opinion of these people on such a matter, however, is of no great value, as the following circumstance shows. Mr. H. R. P. Carter, when living at Madras, repeatedly, as he tells me, allowed the Solpuga, in the presence of natives, to bite his arm until the blood ran, without suffering anything worse than a passing pain from the wound. But although his experiments proved conclusively to himself the harmlessness of the bite, they were not sufficient to make the onlookers alter their judgment one whit. In confirmation of Mr. Carter's conclusion it may be added that Mr. J. ffolliott Darling has also had the fortitude to make similar experiments on himself, and has attained similar results, with species that are found in South Africa.

Of their enemies we know but little. From an observation made by Mr. Distant, who, while in the Transvaal, saw a wagtail attacking a specimen of *Solpuga hostilis*, a small species which is abundant in that country and in Natal, it may be inferred that they are eaten by insectivorous birds, and probably also by some mammals and reptiles. So, too, may it be supposed that the larger kinds of Solpuga destroy the smaller, and that all, both great and small, fall victims to large and medium-sized scorpions, to say nothing of great spiders and carnivorous ground beetles, many of which would certainly be powerful enough to overcome the weaker species.

It must be remembered, too, that although when fasting their agility is amazing, and their chances of escape correspondingly great, yet when gorged with food, as described above, and practically unable to trail their distended bodies behind them, they would fall easy victims to enemies much weaker and slower than themselves.

---

[1] This name for the Solpuga in the Tamil language I venture to spell as I have heard it pronounced.

On the other hand, we learn from Dufour that the species found in Algeria are exempt from the attacks of the Mason wasps, which, as is well known, in that and in all countries fearlessly attack and destroy numbers of the largest spiders, and could, without difficulty, catch the fleetest Solpuga in the world. The reason for this freedom from persecution is not quite clear, unless it is to be explained by the fact that the Solpuga is too formidable a foe for the wasp to tackle. That this may well be the case is rendered intelligible by the reflection that the large lycosiform and mygaloid spiders fall easy victims because, owing to feebleness of vision and lack of activity, they are not quick enough to elude the final swoop of the wasp. The Solpugas, on the other hand, as compared with the spiders, are exceedingly agile and keen-sighted. Moreover, when on the defence, they have a habit, as described by Dr. Walter, of turning up the abdomen, so as to protect that vulnerable part, and extending the legs forwards and upwards in such a way as to present to the foe a pair of gaping jaws surmounted by five pairs of strong limbs armed with long bristles, stout spines and sharp claws. Small wonder if under the circumstances the wasps think discretion the better part of valour.

The last peculiarity to be mentioned is the presence on the inner surface of the jaws of some strong horny ridges, which by mutual friction emit a harsh grating noise. In some genera these ridges are scarcely at all developed: in others they are very pronounced. That the sound is produced in the way described under the stimulus of sudden fear or irritation was long ago pointed out by Hutton, and even before him by Pallas; and, touching its function, one can only suppose that, like analogous organs found in the rattlesnake and in some of the largest spiders and scorpions, it acts as an advertisement of the whereabouts of the Solpuga, and as a warning to enemies to keep a respectful distance.

R. I. POCOCK.

THE LABOULBENIACEÆ: A NEW FIELD OF STUDY AMONG FUNGI.[1]

THE knowledge of most botanists of the group of Fungi here under treatment is probably confined to the brief description given of them by De Bary, under the head of "Doubtful Ascomycetes," where Peyritsch's figures of *Stigmatomyces Baeri* are reproduced.

Since 1884, when De Bary's "Fungi" appeared, the investigation of the group has, however, proceeded apace; and whereas at that time hardly more than a dozen species had been distinguished, Dr. Thaxter considers that no fewer than 150 species belonging to 30 genera are now known. Almost all of these additions are due to Dr. Thaxter's investigations, and have already been announced, from time to time, in a series of papers emanating from the Cryptogamic Laboratory of Harvard University.

The first to observe one of these Fungi was probably the entomologist Laboulbène, in whose honour *Laboulbenia rougetii* was named by Montagne and C. Robin. The earliest description came from Robin in the "Histoire Naturelle des Végétaux Parasites" in 1853. H. Karsten (1869) and Peyritsch (1871–75) followed with a more detailed treatment of the morphological characters of the group, and still later Berlese, Giard, Istvanffi, and Thaxter, have in turn added to our knowledge of the family.

The Laboulbeniaceæ are, without exception, entomogenous, and occur upon species of beetles and flies almost exclusively. They are attached to the chitin of the insect by only a minute foot, by means of which, however, they absorb all the nutriment they require for their development. Upon examination with a hand-lens, they have the appearance of hairs or bristles of a dark colour, standing out vertically from the substratum. As they seldom exceed half a millimetre in length, it is not surprising that they easily escape the notice of entomologist and mycologist alike.

Their morphological characters present features of unusual interest, inasmuch as they seem to exhibit a marked sexuality, and that of a peculiar type. The male cells are non-motile spermatia, arising for the most part endogenously, but in certain genera abstricted exogenously, as in the case of the Florideæ. These spermatia become attached to trichogynes, whose cell-wall appears to have the same gelatinous consistence as have those of the Florideæ. In some genera, these trichogynes become branched and multicellular; in a few cases they bend over to come into contact with spermatia *in situ*, and then straighten again, carrying off a detached spermatium. Bearing the trichogyne is a "trichophore," itself resting on a "carpogenous" cell. From this latter there are ultimately budded off four or eight asci, each containing, when mature, four or eight usually septate ascospores, the whole being enclosed in a fusiform fructification, recalling the perithecium of a Pyrenomycete. It seems impossible to resist the impression that the asci arise as the result of an act of fertilisation, though the details of the process have not been observed. That the Laboulbeniaceæ are to be included among Ascomycetes can no longer be doubtful, and their morphology, when considered in connection with the observations of De Bary, Janczewski, Stahl, and more recently Harper, lend support to the view that sexuality persists in this class of Fungi. It is difficult to imagine how otherwise Brefeld can account for the structure of Laboulbeniaceæ, when his researches have extended thus far.

The similarity in the method of fertilisation with that existing in Florideæ is very marked. For the occurrence of a receptive trichogyne and detached non-motile spermatia among Fungi, Stahl's observations had already prepared us, though it has been denied that the structures called by these names in Collemaceæ, have the sexual significance they have been shown to have in Florideæ. The analogy of the similar organs in Laboulbeniaceæ with those of Florideæ would seem to be beyond doubt. A further startling analogy with Florideæ is found in the occurrence of a single conspicuous pit in the walls separating successive cells of the hyphæ; and, as in Florideæ, these have already been utilised in tracing the genetic connection of the cells of the thallus. Although Thaxter, on account of these similarities, does not regard the derivation of Laboulbeniaceæ from Florideæ, as unworthy of consideration, it is improbable that they indicate anything more than similarities of adaptation, which often occur in widely separated groups.

Of the 250 different species of insects on which these Fungi have been found parasitic, 241 are Coleoptera, and of these the majority are aquatic or riparian in habit. Of the 7 dipterous host-species one is the common house-fly, which is frequently infested with *Stigmatomyces Baeri* in the neighbourhood of Vienna. The single termite affected came from Africa, and the single acarid from Paraguay. Though most of the Laboulbeniaceæ yet described are exclusively North American, 19 European species are known, and some accompany their hosts into two or three continents. It is probable that the family will be found to be numerous in species, and widely distributed in range. No British locality for a single species is given in Dr. Thaxter's work, and no British writer seems to have yet made any contribution to the literature of the group. In Dr. Cooke's "Vegetable Wasps and Plant Worms," published in 1892, the species then described by Thaxter and others are enumerated, but no discovery of any of these in Britain seems to have been known to the author. It is highly improbable, however, that none of the parasites occur on any of the more than 3000 British species of Coleoptera.

Though these plants do not at present appear likely to become of any economic importance, yet it is clear that they are of exceptional morphological and physiological interest; and Prof. Thaxter has earned our gratitude for the persistence with which he has pursued their study, and for the ability and skill with which he has described and portrayed them. The work forms a worthy successor to the author's monograph on "The Entomophthoreæ of the United States."

THE BOLOMETER.[1]

IN the number of the *American Journal of Science* for March 1881, there appeared an article descriptive of the actinic balance (since called the Bolometer), an instrument which has gained acceptance among physicists as a useful aid in the study of radiant heat. It was, it may be remembered, originally devised by the writer to discriminate the heat in any small portion of the grating spectrum, but it has since found wider applications.

---

[1] Reprinted from the *American Journal of Science*, April. (Communicated by the Author.)

As at first constructed, the strips, representing arms of the Wheatstone bridge, were made of iron from 0·001 to 0·0001 of an inch in thickness. The instrument was, even under these initial conditions, very many times as sensitive as the best thermopile the writer then possessed, but there does not appear to be any definite statement as to the exact sensitiveness in its early form.

In the article referred to, however, the instrument is represented as giving a deflection of about 40 scale divisions (millimetres) from the lunar heat, concentrated by a thirteen-inch lens, and it was sufficiently accurate to give a probable error of rather less than one per cent. for a single observation on a constant source of heat, so that the accuracy of the bolometer (quite a distinct consideration from its sensitiveness) was even then as great as that of the best photometric process. The galvanometer in use at that time was one of the early Thomson pattern made by Elliott.

The first bolometers were made by the writer's own hands. Subsequently the strips were usually cut out from sheets of thin platinum, and in one or two instances made from flatted wire, the strip of the linear bolometer at that time (about 1883) being usually about 10 millimetres long; anywhere from 0·001 to 0·01 of a millimetre thick, and, according to its special purpose, being made from 1 millimetre to 0·1 millimetre wide.

About 1886 the mounting of the instrument had been improved by the writer, so that the strip appeared like the vertical "wire" of a reticule in the focus of a positive eye-piece. It was also movable in some cases by a micrometer screw, and was, in fact, a micrometer thread controlled in the usual way, but endowed with the special power of feeling the radiations from any object on which it was directed.

In the earliest spectrum work the bolometer developed another important quality, its "precision." This quality is quite independent of the accuracy with which it repeats measures of radiation or any constant source of heat, and concerns the precision of setting, as a micrometer thread. It could, even twelve years ago, be pointed, not only like the thermopile, within a fraction of a degree of the place of the source of radiation, as for instance on a bright line in the spectrum, but within a fraction of a minute of arc.

The instrument of course depends for its general efficiency on the galvanometer with which it is connected. That used in 1886[1] had several improvements due to the suggestions of Sir William Thomson and Prof. Rowland, and was perhaps, at that time, the most effective instrument of its kind in use for such a purpose, the mirror and needles having been specially constructed at the Allegheny Observatory. The mirrors were platinised by the kindness of Prof. Wright, and were at that time nearly a centimetre in diameter. The needles were hollow magnets made by Mr. Very of the Allegheny Observatory. For the damping mechanism of the older galvanometer, I had substituted a dragon-fly (*Libellula*) wing, in which nature offers a model of lightness and rigidity quite inimitable by art. At that time, when making a single vibration in 20 seconds, a deflection of one millimetre division of the scale at one metre distance was given by a current of 0·000,000,0005 amperes, the instrument as described being capable of recording a change of temperature in the bolometer strips of less than 0·00001 of a degree Centigrade. So much less than this could be observed by special precaution, that it might be said that this one one-hundred-thousandth of a degree was not only indicable but measurable by the apparatus, which was employed as described, in the determinations of the relations of n to λ for the rock-salt prism, and by which the infra-red spectrum was at that time followed by actual measurement, to a wave-length of rather over five one-thousandths of a millimetre.

Since then the bolometer has been used in various researches, of which some occasional account has been given in the *American Journal of Science*. (See numbers for November 1888, and August 1890.) During recent years it has been specially employed in making a bolographic map of the lower spectrum, the publication of which has been greatly delayed by conditions incidental to the relations of the Smithsonian Observatory with the Government, but which it is hoped will not be deferred much longer.

Without here entering into an account of the work done by it, I have thought that it might be of interest to give very briefly a statement of the present condition and form of the instrument itself, considered under three aspects.

(1) Its precision, or the degree of exactitude with which it can be set on a special point, as, for instance, on a line of the invisible spectrum, recognised by its heat radiation alone.

(2) Its accuracy, or its capacity for repeating the same measure of radiation under like conditions.

(3) Its sensitiveness, or capacity for detecting minute radiations.

The instrument which I will take as the subject of comparison with the earlier one as described in this *Journal* (August 1886), is now in use in a chamber automatically kept at a temperature constant within one-tenth of a degree Centigrade.

The strips, the essential part of the instrument, are in the present case made by Mr. C. G. Abbot, and are of platinum, the central one being rather less than 0·1 of a millimetre wide. (The case is now made of metal instead of ebonite, and is surrounded by a current of water).

It is quite possible to make bolometer strips much narrower, but this is less necessary with the employment of the long-focus, image-forming mirror, so that in the present case the strip is at such a distance that it subtends an angle of 3·4 seconds Its angular aperture is in practice adapted to that of the slit, which, with the use of the long collimator employed by the writer, gives a capacity of pointing (pointing, that is, *in the dark*), with a probable error of little over a second of arc. Quite recently, owing to the use of a novel collimating system of two cylindrical mirrors proposed by Mr. Abbot, the slit, though at a moderate distance, can have an opening sufficient to avoid prejudicial diffraction effects, while subtending an angle of considerably less than one second of arc.

In the galvanometer, the use of the fine quartz threads and specially small mirrors, originally due to Mr. Boys, has lately been carried to what seems near the practicable extreme, the quite invisible thread being made some 30 centimetres long, the mirror 2 millimetres in diameter, and weighing but 2 milligrams, and its six needles, of proportionate weight and dimensions.

This system is now made to serve with a much shorter swing than that formerly employed. If we reduce it to a time of single vibration of 20 seconds, only for the purpose of comparing it with the values already given in the earlier form, we obtain the results submitted below.

Before giving them, however, it is to be mentioned that the apparatus at Washington is most unfavourably situated, owing to its being subject to tremor from the traffic of neighbouring streets and to other causes, which it has been the object of years of struggle to conquer. This has been so far done that the values presently to be given (which, it will be remembered, are only attainable in a chamber of constant temperature, with special precaution against disturbance from external tremor), can be counted on as real values, always obtainable under proper conditions, and, in fact, rather within than without the average working capacity of the instrument.

I here consider the bolometer as at present employed.

(1) With regard to its precision, or exactness of pointing. The old thermopile could be set on a portion of the spectrum only with an error of a considerable fraction of a degree. The linear bolometer as employed in 1886 could be set with a probable error of a fraction of a minute of arc. The bolometer as employed to-day, and moved through the spectrum by clock-work, can be automatically set with a probable error of a single observation of little over a second of arc, can be set, that is, in the dark with a precision little inferior to the capacity of the eye in setting a micrometer thread in the light.

(2) As to its accuracy. I have had occasion recently to take a series of measures of successive throws of the galvanometer, using as a source of heat an Argand petroleum flame in a common student's lamp. I had no photometer at hand, but taking the usual statements of the text-books as to the accuracy of vision, it might be expected that such measures with the eye would give a probable error of about one per cent. (This is where sources of light of similar quality are compared.) The probable error of a single galvanometer reading was between 0·03 and 0·04 of one per cent., and this included the fluctuation of the intensity of the source of radiation, and the error of estimating tenths by the reader on the scale, both quantities of nearly the same order as the error in question. It seems safe to say, then, that *no* error attributable to inaccuracy of the bolometer could be detected by the means employed.

(3) As to sensitiveness. In the early work, for a time of single swing of 20 seconds, a deflection of one millimetre with

---

[1] *American Journal of Science*, third series, vol. xxxii. p. 90, 1886.

the scale at a metre's distance was obtainable with a current of 0·000,000,0005 of an ampere. At present, under such circumstances, a similar deflection would be obtained with 0·000,000,000,0012 ampere, that is to say, the apparatus is about 400 times as sensitive as it was when first described.

At present the bolometric apparatus, under the conditions already cited, will indicate a change of temperature in its strips of, at any rate, much less than one-ten-millionth of one degree Centigrade. S. P. Langley.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Mrs. Phebe Hearst has offered to erect for the University of California a new building for the School of Mines.

Draughtsmen and engineering students familiar with the principles of the science of steam, are given opportunity of advancing their knowledge by a special class in steam-engine trials which will commence at the South-Western Polytechnic, Chelsea, on May 17, and terminate on June 28. The class will be conducted by Mr. W. W. F. Pullen and Mr. H. A. Clark.

The trustees of Cornell University have just established a Medical Department and a State College of Forestry. The medical department will be situated in New York City, and its faculty will be made up principally of those surgeons and physicians who have heretofore been connected with the medical department of New York University; including all but three of the instructors of that department. The endowment of the new medical school is by a donor whose name is not disclosed. The College of Forestry established by Cornell University will be situated at Ithaca, and called the State College of Forestry, having been authorised and endowed by the State with a grant of 10,000 dollars by the legislature which adjourned a few days ago. Prof. Bernard E. Fernow, director of the United States Division of Forestry, has been made director of this department.

One of the most important educational problems at the present time refers to the coordination of the work of the University and Technical Colleges with that of other educational institutions in the neighbourhood. It is unfortunate that in several cities the educational institutions are competing with one another instead of working together as an organic whole, in which each part has a definite function to perform. Efforts are, however, being made in the large provincial centres to prevent the undesirable overlapping which at present exists, in order to make the various educational institutions complement each other's work without competition. Summaries of what has been done in this regard at Birmingham, Manchester, Plymouth, and Sheffield appear in the current number of the *Record of Technical and Secondary Education*. In Birmingham, though no formal machinery exists for the coordination of educational work, the various institutions have adapted their organisation to the circumstances of their environment, supplying any need that was felt, and avoiding duplication of function. An educational ladder has, in fact, been constructed, up which a boy may climb from the Board School to the highest University honours without exciting the jealousy of other schools than those which he attended. This event actually occurred last year, when Mr. W. H. Austin, who began his education at a Birmingham Board School, came out Senior Wrangler at Cambridge. In Manchester the provisions for coordination take the form of an agreement between the Technical Instruction Committee of the City Council and the School Board, and between the authorities of Owens College and the Manchester and Salford Technical Schools. As between Owens College and the Technical Schools it is arranged that the latter shall aim at demonstrating how the general principles of science and art may be applied to the advancement of trade and industry, whilst the college will eschew these obviously bread-and-butter subjects, and address itself to the higher walks of pure science. In Plymouth, also, a scheme has been arranged which correlates and connects the whole of the science and art teaching of the town, from the infant school upwards. In Sheffield a scheme which secures the effective coordination and economical management of the Board Schools, the Technical School, and the School of Art, has been at work since last September, and appears to give entire satisfaction to all concerned; and Bradford has just taken steps to grade its various educational forces. Through all the schemes one main principle runs—that, namely, of making the common schools, Primary and Secondary, the kindergarten and nursery of science and art, and of making the Technical Schools true to their name as the places where is taught the application of science and art to the purposes of industry and commerce, while to the University Colleges are allocated the higher scientific studies. These examples should encourage other county boroughs to consider and adopt educational schemes which will prevent waste of effort and do away with conflicting interests.

SOCIETIES AND ACADEMIES.

London.

Physical Society, April 22.—Mr. Shelford Bidwell, F.R.S., President, in the chair.—A paper by Prof. T. C. Porter, on a method of viewing Newton's rings, was read by Prof. S. P. Thompson. If a parallel beam of light from a rectangular slit falls at oblique incidence upon a plane plate of glass, the first two reflections occur at the upper and lower surfaces of the glass, respectively, and give two corresponding images that may be formed on a screen. If now a second glass plate is added below the first, and parallel to it, at a short distance, four images of the slit appear on the screen. But when the lower plate is brought into contact with the upper one, the reflection from the lower surface of the upper plate follows the same path as that from the upper surface of the lower plate, so that only three images are now to be distinguished. For the two glass plates the author substitutes a "Newton's rings" apparatus, and by the above device for eliminating a set of reflections he is able to restrict the illumination to the light that comes from the two interior surfaces. As thus observed, the colours of the rings are very brilliant. When the plates are very clean, the darkest area of the "black" spot has a sharply-defined edge, similar to that of the black film of a soap-bubble. By using monochromatic light, the various sets of rings may be photographed; they appear as several systems of concentric circles, the systems intersecting one another. This method of illumination by a slit, enables Newton's rings to be viewed free from all light except that due to reflections at the bounding surfaces of the air-space between the plates. It reveals to the eye the subordinate interference-systems that coexist with the primary rings, and it demonstrates which of these reflections must be taken into account in the theory of the phenomenon. Moreover, it supplies a means for analysing these systems, and it indicates that the interference of monochromatic light is never complete under these circumstances. Prof. Herschel said it was rather difficult to follow the arguments of the author without witnessing the phenomena. Much complication was introduced by the successive reflections; it was not clear what became of them. There was no doubt as to the advantage of a narrow slit for the illumination. He thought some of the secondary reflections might be got rid of by using plates that were slightly prismatic. Prof. Thompson had, in his own laboratory, verified the advantages of the author's method of illumination. The result was a very sharply-defined first system of rings. Curves of subordinate interference were easily to be observed by this arrangement. Prof. Boys noticed in the photograph of the ring-systems that the independent systems of bands were distorted at the points of intersection. The intersecting curves formed a sort of honeycomb, or hexagonal system, instead of a system of curvilinear quadrilaterals. This distortion reminded him of similar effects observed in the photographs of "ripples." Mr. Edser said he had often noticed similar distortions, but he had always been able satisfactorily to explain them as being the result of imperfect focussing. The author had referred to the fact that a thin film when viewed by reflected light appears black. A phase-change of half a wave-length takes place either on reflection at a rarer, or at a denser medium; but there is no information from which to decide between these two alternatives. The truth of the assumption that the phase-change occurs at the denser medium seems to depend, so far as experimental evidence is concerned, upon the observation that in Lloyd's bands the central one is black. To produce the Lloyd's bands only one mirror is used; the bands produced by Fresnel required three mirrors. Wernicke performed an interesting series of experiments in which white-light reflected for various angles of incidence from a thin sheet of glass was examined spectroscopically. The spectrum was crossed by numerous black bands, and from the position of these bands in the spectrum the thickness of the glass was calculated. The calculated thickness when the angle of incidence was great, differed from that obtained with small angles of incidence; the conclusion was that when light is internally reflected, even at an angle of incidence less than the angle of total reflection, a phase-change is produced. If the space between the two plates in Prof. Porter's experiment were filled with a substance of higher refractive index than glass, a confirmation or otherwise, of this result might be obtained.—Dr. S. P. Thompson then exhibited a model apparatus made by the Helios Company to illustrate the three-phase method of transmitting power. It consists of a small generator, driven by hand, and a small motor. The generator may be separately excited by a secondary battery; it has three independent coils. The six ends of the coils are connected to six commutator rings. The motor has three corresponding pairs of opposite coils; these can be grouped in various ways for connection to the brushes of the generator. The six coils are on a hinged frame, so that, if necessary, they can be laid down flat, for other rotation experiments. Two armatures are provided, either of which may be used. The first is an iron wheel with peripheral copper bars arranged like a squirrel-cage; the other is a simple iron disc without added conductors.—The President proposed votes of thanks, and the meeting was adjourned until May 13.

Zoological Society, April 5.—Lieut.-Colonel H. H. Godwin-Austen, F.R.S., Vice-President, in the chair.—Prof. Sydney J. Hickson, F.R.S., read a paper on the species of corals of the genus *Millepora*. The author stated that thirty-nine species of the genus *Millepora* had been described. A prolonged investigation of the characters hitherto used for the determination of the species had proved them to be all unsatisfactory. An examination of the soft parts of a great many specimens of several forms of growth and from widely distant coasts had revealed no features that could be used for separating species. In the author's opinion, therefore, there was only one species of this genus now living, and that the individuals of this species were capable of assuming a great variety of form, according to the conditions in which they lived.—A communication was read by Mr. J. Stanley Gardiner containing an account of the perforate corals collected by him in the South Pacific. Fifty-one species were treated of, of which fifteen were described as new.—Mr. Oldfield Thomas read the description of a new Dik-dik allied to *Madoqua kirkii*, but much larger, which had been obtained by Mr. H. S. H. Cavendish in the region of Lake Rudolf, and was proposed to be called *Madoqua cavendishii.*—Mr. R. Lydekker, F.R.S., made some remarks on the geographical races of the Banting (*Bos sondaicus*), and suggested that the Burmese and Manipur forms of this animal should be given subspecific rank, for which he proposed the respective names of *Bos sondaicus birmanicus* and *B. s. woodi*.

Entomological Society, April 6.—Mr. R. McLachlan, F.R.S., Vice-President and Treasurer, in the chair.—On behalf of Mr. Greenshields, Mr. Jacoby exhibited specimens of the longicorn beetle, *Micropsalis durnfordi*, Burm., from Patagonia. Mr. Greenshields, who was present, stated that this species, remarkable for the great development of the palpi, was originally taken by Darwin; his own examples were taken hiding in thorny bushes in a dry watercourse.—Mr. Champion exhibited European examples of *Harpalus fröhlichi*, a newly-discovered British species.—Mr. B. O. Bower showed living larvæ of *Caradrina ambigua*, an insect which had recently occurred in England in countless numbers. They were bred from ova laid by a female taken on the South Devon coast, and fed indiscriminately on low plants.—Mr. M. Burr read a paper supplementary to Mr. Green's previous communication on *Dyscritina*, and definitely referred the imagos to the genus *Diplatys*, *D. longisetosa*, Westw., being a good species, and Mr. Green's new form proving to be *D. nigriceps*, Kirby.—Dr. Chapman read a paper on the larva of *Eriocephala allionella*, which he stated to be essentially similar to that of *E. calthella*, previously described by him.

Linnean Society, April 7.—Dr. A. Günther, F.R.S., President, in the chair.—Mr. J. E. Harting exhibited specimens of the Asiatic partridge, *Perdix daurica*, of which a large consignment had been lately received in London. Mr. W. E. de Winton, who brought another specimen of this bird for exhibition, made some remarks on the geographical distribution of the species, and expressed the opinion that it had been improperly described by certain writers as Manchurian, its true habitat lying to the west of the Khinghan Mountains in Mongolia.—Mr. J. E. Harting also exhibited the skin and skull of a wild cat, *Felis catus*, recently obtained near Speanbridge, in Inverness-shire. He pointed out the present restricted range of the animal, which had not only disappeared entirely from England and Wales, but was no longer to be found in Scotland south of a line drawn from Oban to Ben Lui, along the southern and eastern boundary of Perthshire, and thence northward to Nairn. He explained the cause of reversion in the colour of emancipated house-cats to the wild type of *Felis catus*, and referred to the skulls of cats which had been exhumed on the site of the Roman city of Silchester, which he thought disproved the view of the late Prof. Rolleston (*Journ. Anat. and Physiol.*) to the effect that the domestic cat was not known to the Romans.—Dr. G. Elliot Smith read a paper, entitled "A contribution towards a more exact knowledge of the anatomy of the brain in Edentata." A full account of the brain of *Orycteropus* was first given, and comparisons were instituted with that of a dozen species representative of the leading Edentate families, including *Manis* and *Chlamydophorus*.—A paper was read by Mr. H. Farquhar, of Wellington, N.Z., on some New Zealand *Actiniaria*, in which he described a new genus, *Halcampactis*, and species *Halcampactis mirabilis*, together with the following new species: *Edwardsia elegans* and *neo-zelanica*; *Corynactis Haddoni*, *mollis*, and *gracilis*; and *Actinia tenebrosa*. *Halcampactis mirabilis* he regarded as of special interest, since it appeared to form a link between the *Sagartidæ* and *Halcampidæ*, which had hitherto been widely separated by systematists.

Royal Meteorological Society, April 20.—Mr. F. C. Bayard, President, in the chair.—Major H. E. Rawson, R.E., read a paper on anticyclonic systems and their movements. Cyclones and anticyclones have long been recognised as powerful weather controls, and their movements studied, but up to the present very little has been written in this country upon the progressive movements of the cores of the permanent high-pressure areas which are found to be associated with certain localities at different times of the year. The author referred to previous investigations by Abercromby, Scott, Loomis, H. C. Russell, and Buchan, and then proceeded to give the results of an examination which he had made of all the available synoptic weather charts for the eleven years 1881 to 1891. During this period there were 212 cases in which the centre or core of an anticyclonic system was over the British Isles, and of these 130 were due to the Atlantic system, 41 to the Scandinavian, and 17 to the Greenland, 22 to the Atlantic and Scandinavian systems extending and merging together, and 2 to the same thing occurring in the case of the Atlantic and Greenland systems. It is thus evident that we owe the greatest number of our anticyclones to the Atlantic system. They occur in all months, but more especially in January, June and October, and are least frequent in April and November. When such anticyclones move away from our area the direction is very much influenced by the season of the year, by far the largest number drift off in some direction between north-east, through east to south, and take the more southerly course in December, January and February Some few between April and July move west or south-west, and still fewer north or north-west.—The Hon. F. A. Rollo Russell described the results of observations which he had made on haze and transparency during 1897. He found that the greatest clearness occurred with winds from the westward, and the least clearness with winds from the eastward. The highest mean visibility was 24 miles with the west winds, and the lowest mean visibility was 10·6 miles with north-east winds.

Paris.

Academy of Sciences, April 18.—M. Wolf in the chair.—Expression of tidal coefficients by means of a sum of periodic terms, by M. Hatt.—On the reduction of double integrals of algebraic functions, by M. Émile Picard.—On some derivatives of tetra-methyl-diamido-benzophenone, by M. E. Grimaux. The dinitro- and dibromo-derivatives are described, and colouring matters produced from them.—Sugar and fat from the point of view of their respective nutritive value, by M. A. Chauveau. In these cases the subjects under experiment were kept at rest; the results were similar to those obtained in the previous experiments, the sugar diet being always superior to the thermally corresponding fat diet.—The committees were nominated for awarding in 1898 the prizes bearing the names of Wilde, Vaillant, Desmazières, Montagne, La Fons-Melicocq, Thore, Savigny, Montyon (medicine and surgery), Bréant, and Godard.—On the ellipsoid of Jacobi, by M. P. S. Krüger.—On the motion of a heavy body of revolution, suspended from a point on its axis, by M. E. Jahnke.—On the potential functions of the theory of elasticity, by MM. Eugène and François Cosserat.—On the transport of luminous variations by means of a wire conducting electricity, by M. Dussaud. An application of the selenium cell.—On the influence of self-induction in the explosion by the electric spark of mixtures of marsh gas with air, by MM. H. Couriot and J. Meunier.—Influence of temperature upon chemical reactions, by M. Albert Colson. An experimental study of the effect of temperature upon the velocity of absorption of hydrogen sulphide by orthophosphate and pyrophosphate of silver, zinc phosphate, and copper phosphate.—On the ammoniacal bromides of silver, by M. Jarry. By the action of liquid ammonia upon silver bromide the two compounds $2AgBr.3NH_3$ and $AgBr.3NH_3$ are formed, the dissociation pressures of which were measured.—On the phosphoric ethers, by M. J. Cavalier. Monomethyl- and monoallyl-phosphoric ethers were prepared and their behaviour towards indicators examined. The results were analogous to those given by the corresponding ethyl ether. A table is given showing the heats of neutralisation of the three ethers by various bases.—On the alkaline sulphantimonites, by M. Pouget. The sodium sulphantimonites are formed under conditions analogous to the potassium compounds; they differ from the latter, however, by the facility with which they undergo oxidation to sulphantimoniates.—General reaction of ethylenic hydrocarbons; corresponding mercuric combinations, by M. G. Denigès. By treatment with acid mercuric sulphate, all ethylenic compounds (except ethylene itself) give yellow compounds of the formula $(HgSO_4.HgO)_2R''$, where R'' represents the hydrocarbon. Compounds of propylene, butylene, and amylene are described.—Heat of formation of some quinones of high molecular weight, by M. Amand Valeur. The quinones used were: α-naphthoquinone, β-naphthoquinone, anthraquinone, phenanthrenequinone, and retenequinone; the results are compared with α- and β-naphthols, new data for which are given.—Heats of neutralisation of ethylphosphoric acid, by M. G. Belugou.—New synthesis of 3·3-di-methyl-1·5-pentanedioic acid, by M. F. E. Blaise.—Spectrum analysis of non-conducting substances by fused salts, by M. A. de Gramont. The finely-powdered mineral is fused with either lithium carbonate, boric acid, or potassium bisulphate, the first for preference, and the sparks passed through the molten mass.—On the functions of cerebral hypophysis, by M. E. de Cyon. The slightest pressure upon the hypophysis is immediately followed by a sudden variation in the blood pressure, and by a marked decrease in the number of heart beats per minute.—Effects upon man and mice of the inoculation of a pyogenous Tricophyte, by MM. Sabrazès and Brengues.—The parasites of cancer and of sarcoma. Coloration, structure, cycles of reproduction, and dimorphism, by M. F. G. Bosc.—Contribution to the study of direct cellular division; its anomalies and functional value, by M. Joannes Chatin.—On the Annelids collected by the expeditions of the *Travailleur* and *Talisman*, by M. Louis Roule.—On a cavity in the integument serving in the *Myrmicinæ* to spread out a secretion product in contact with air, by M. Charles Janet.—Variations, in four phases, of the pressure and of the two mean components of the wind on the meridian of the sun and its orthogonal, by M. A. Poincaré.—Influence of the movements of the moon on the oscillations of the atmosphere, by M. P. Garrigou-Lagrange.

DIARY OF SOCIETIES.

THURSDAY, April 28.

Royal Society, at 4.30.—On the Meteorological Observatories of the Azores: H.S.H. the Prince of Monaco.—A Compensated Interference Dilatometer: A. E. Tutton.—Observations on the Action of Anæsthetics on Vegetable and Animal Protoplasm: Dr. Waller, F.R.S., and Prof. Farmer.—A Calorimeter for the Human Body: Dr. Marcet, F.R.S.—An Experimental Inquiry into the Heat given out by the Human Body: Dr. Marcet, F.R.S., and R. B. Floris.
